Having just completed the writing of a history of the first 50 years of the Nuffield Provincial Hospitals Trust, I was interested in Dr Stephen Frankel’s stimulating editorial in your December issue, especially so since it also has some relevance to the recent correspondence in the Journal of Public Health Medicine about health service research. My interest is because until the advent of the Health and Social Services Department on the scene, an event which was especially noted by Sir George Godber and Dr Richard Cohen in the publication commissioned by the Trust, Portfolio for health,¹ the Trust perhaps financed more of what has come to be known as “health services research”, which included support for epidemiologists, than any other body.

During that period and indeed since, I have been struck by the record unearthed by my explorations for the History, which has been sobering to the extent that so much of the research sponsored and the findings published has gone unheeded. The current obsession with the “reforms” obscures a wealth of “indications” of how to improve the public health.

It is not my intention to comment in detail on Dr Frankel’s observations even if (schooled by the

Trends in hospital admissions for asthma in Lombardy, Italy, 1976–86

Substantial changes have been registered in death certification rates from asthma over the last few decades, and appreciable rises have been observed in most recent years in several developed countries, including New Zealand, England and Wales, and Italy.¹–³ These changes have been related to the introduction and use of newer pharmacological treatments, and the recent upward trends to serious acute side effects of some specific formulations, or to the delay caused by these drugs in seeking appropriate treatment of acute severe asthma.⁴–⁹ This would suggest that the upward trends in asthma mortality are not necessarily a consequence of increased incidence and prevalence of the disease, and should not therefore be consistently reflected in other asthma statistics.

To shed further light on the issue, we have considered trends in hospital admissions for asthma between 1976 and 1986 in Lombardy, the most populated Italian region, with approximately nine million inhabitants. Records of hospital admissions for asthma in Lombardy for the period 1976–86 were obtained from the Regional Department of Epidemiology. From these data, and the corresponding estimates of resident population, age specific and age standardised admission rates were derived. Directly standardised rates were based on the European standard population.

Trends in overall age standardised hospital admission rates for asthma between 1976 and 1986 are presented in the figure and contrasted with national mortality rates over the same calendar period. In both sexes, there was no apparent trend in hospital admission rates over the calendar period considered. When age specific rates were considered, however, appreciable rises were observed in childhood (over 40%, in both sexes), while there was no change in young adults (15–44 years) and noticeable declines in middle and older ages (table).

The interpretation of these trends is not simple, particularly with reference to the different patterns in various age groups, but nonetheless recent trends in admission rates for asthma in Lombardy are substantially different from certified mortality on a national level. Over a comparable calendar period, in fact, overall age

Epidemiology of indications.
