Rethinking the terms non-communicable disease and chronic disease

We welcome Ackland et al’s timely discussion on the terms “non-communicable” and “chronic” disease. Their argument is that conditions currently labelled “non-communicable” are in fact “communicable” because the risk behaviours that underlie them are highly transmissible. They argue for a change in label, from “non-communicable diseases” to “chronic diseases”.

Their argument, however, confuses one classification system, which is based on cause (namely, communicable diseases compared with non-communicable diseases compared with injuries), with a second classification system, which is based on effect (namely, acute conditions compared with chronic conditions). Their argument also overlooks the growing consensus that chronic conditions include certain communicable diseases, such as HIV/AIDS. In fact, certain non-communicable conditions are acute in nature, while certain communicable conditions require chronic, ongoing care. For example, HIV/AIDS clearly has an infectious aetiology but requires long term management by the healthcare system. As such, it has a great deal in common with type 2 diabetes. Conversely, acute appendicitis is a “non-communicable disease” that requires an urgent health care response quite similar to bacterial meningitis.

A comparison has been made of the burden of communicable and non-communicable diseases in children. We are seeking a shift towards more appropriate use of terminology when describing the major disease states.

Authors’ reply

The letter by Unwin et al in response to our paper makes some important points about the attributes of disease classifications.

We agree that, unfortunately, it is commonplace for classifications based on cause and those based on effect to be interchanged by the public health community. This not only causes confusion in the minds of public health policy makers, but promotes bureaucratic apathy towards resourcing prevention programmes for diseases that contribute so significantly to the burden of disease. Why would a jurisdiction dedicate scarce resources towards preventing and controlling diseases that are long term (chronic) and where causation is unclear (non-communicable)? Many jurisdictions will only take on the concept of an epidemic seriously when there is a clear link to the traditional concept of “communicable” or infectious disease.

So it is very important to encourage use of language in describing diseases that is of practical value to both clinical researchers and policy makers. This language should engage everyone in thinking about public health responses to diseases from both the perspectives of disease prevention and disease control. While international classification systems are unlikely to change quickly, we are seeking a shift towards more appropriate use of terminology when describing major disease states.

Our desire is to encourage people to think about the upstream issues of causation of diseases in order to motivate a more pragmatic focus on public health interventions. Indeed we support use of the term “chronic” to emphasise the long term implications for the health system, but more importantly wish to discourage use of the term “non-communicable” where there is mounting evidence for the non-microbial, communicable nature of many chronic diseases. Qualifying some chronic diseases as being “transmissible” may be helpful in highlighting the role of social, cultural, and societal factors as disease vectors. Herein lie the opportunities for improving public health responses and interventions. We are glad that Unwin et al support our thinking to promote the use of the term “chronic” to denote conditions requiring long term care, which is more readily understood by the public health community.

Epidemiology of SARS: the missing pathogen?

This is indeed a strange disease. The epidemiology suggests it to be of relatively low infectivity, but high severity. This in itself is odd, especially if the causative agent is a virus and the principal mode of spread by coughing/droplet. Also odd is the undoubted existence of “superspreaders”, who can infect very many of their contacts—I can’t think of any parallels to this in respiratory virology. Perhaps the SARS virus obeys the usual rules of droplet transmitted respiratory infections, and is of high infectivity. However, because of shared antigens, a proportion of the population has an acquired resistance to the new virus, having already been exposed to another, relatively innocuous, virus that provides immune protection. It is possible that the proportion of humanity immune or partially immune to SARS could be as high as, say, 95% if the second virus were a very common one, for example, one of the coronaviruses that causes coryza. This would explain the seemingly low, unexpectedly so, infectivity of the SARS agent.
Is the inverse care law no longer operating?

The inverse care law, proposed by Julian Tudor Hart in 1971, states that “the availability of good medical care tends to vary inversely with the need for it in the population served.” A number of authors have now claimed to have found instances of the inverse care law operating in practice. However, subsequent evidence has cast doubt on the general validity of the law. This study aims to assess whether the inverse care law still holds in the current context of healthcare provision.

Siblings and adult mortality and stroke risk

In men born between 1906 and 1938 and screened between 1970 and 1973 a strong relation between greater number of siblings and mortality risks was found by Hart and Davey Smith. These risks, however, were also related to adverse behavioural socioeconomic and health outcomes.

A great number of children, particularly in lower socioeconomic classes and in the earlier decades of the previous century, implies reproduction at earlier and more advanced maternal age, shorter interpregnancy intervals. These aspects have been neglected in studies on number of siblings in relation to constitutational diseases of complex origin. These casualties seem to be connected with non-optimal maturation of ovarian follicles and in fact, the maturing oocytes they contain. Conceptions at the extremes of maternal reproductive age or during the critical stages of postpartum restoration of the ovulatory pattern (or during lactation) are constrained by protraction of the preovulatory phase of the menstrual cycle that entrains preovulatory over ripeness of the oocyte (PrOO). In addition, mothers with low socioeconomic status are known to suffer disproportionately more from low standards of nutrition, abnormal body mass index, and inherent menstrual disorders. They also use less safe methods of contraception resulting in gradually more unplanned and unwanted pregnancies and, in turn, in shorter interpregnancy intervals and intrauterine aging of the oocyte (waiting to be fertilized in the preovulatory phase the ovary, the ovulation)

The driving force behind decreasing rates of newborns with neural tube defects or Down’s syndrome was evident long before the introduction of prenatal diagnosis, selective abortion and folate supplementation. The true reason for these decreases has never been revealed and the biased scientific preoccupation with recent changes in lifestyle and risk factors for explaining the enigmatic decrease of cardiovascular diseases has also been blamed. A same scenario, therefore, may exist here and ovopathy might be the common causal pathway for developmental anomalies and “innate” constitutional entities of complex origin. The relentless decrease of conceptopathology, running parallel with increasing socioeconomic levels and improving healthcare provision, would be responsible for their decrease.

Intrauterine mortality, stillbirth, and infant mortality began to decrease at the end of the 19th century, while in fact, cardiovascular diseases only after a lifetime delay since the 1960s. Many other unexplained correlates with cardiovascular diseases (and other chronic diseases) are elucidated by this causal pathway, for example, comorbidity, intergenerational matrilineal transmission and strong social patterning, discordance in monogamous twins, poor fetal growth and low birth weight, seasonality of conception correlated with geographically latitudinal gradient, and finally, male gender biases.

Global public goods for health; health economic public perspectives

This volume explores the applicability of the concept of global public goods to health and health related issues as well as the question of the added value—for example, in terms of new analytical insights or a better understanding of various policy approaches and instruments—of ‘looking at…things through the lens of global public goods. As the stage setting chapter 1 by Woodward and Smith notes, ‘…as globalization progresses…matters which were once confined to national policy are now issues of global impact and concern; yet no one nation necessarily has the ability, or the incentive, to address the problem’ (page 3). So cross border cooperation is important for a global public good, let us say, polio eradication, to emerge and to be available for the consumption—or enjoyment—of local communities or countries.

The volume’s chapter analyses are written by a multi-disciplinary team of authors and cover three main sets of issues: (1) the global public goods properties of the control or eradication of select communicable conditions (including polo, tuberculosis, antimicrobial drug resistance), and the health consequences of a number of global environmental ‘bads’ (such as the global climate change or the depletion of the ozone layer); (2) the importance of knowledge (including medical knowledge, genomics knowledge, and public health infrastructure and knowledge) as a critical input to people’s improved health status and enhanced public health conditions; and (3) how to enable global public goods for health, such as international law and health regulations. However, running through the individual chapter analyses also are common themes. Among them are such issues as the prioritisation of global public goods and the politics of their provision, their ‘production’ and financing. The discussions on these themes are analytically rigorous yet clear and focused, leading to practical and pragmatic—and in some cases innovative—policy conclusions and recommendations. Thus, the book should be of interest to researchers and students as well as policymakers and practitioners alike.
