BMI, CVD and mortality

**053 COMPARISON OF THE ASSOCIATIONS OF BMI AND MEASURES OF REGIONAL ADIPOSITY WITH CORONARY HEART DISEASE, DIABETES AND ALL CAUSE MORTALITY: A STUDY USING DATA FROM FOUR UK COHORTS**

1AE Taylor, 1S Ebrahim, 2Y Ben-Shlomo, 2IM Martin, 2PH Whincup, 2JW Yarnell, 3SG Wannamethee, 4DA Lawlor. 1Department of Social Medicine, University of Bristol, Canyge Hall, Bristol, UK; 2Department of Epidemiology and Population Health, London School of Hygiene and Tropical Medicine, London, UK; 3MRC Centre for Causal Analyses in Translational Epidemiology, Department of Social Medicine, University of Bristol, Oakfield House, Bristol, UK; 4Division of Community Health Sciences, St. George’s, University of London, London, UK; 5Department of Epidemiology and Public Health, Queen’s University Belfast, Belfast, UK; 6British Regional Heart Study, UCL Department of Primary Care and Population Sciences, Royal Free and University College Medical School, London, UK
doi:10.1136/jech.2009.096727a

**Objective:** To compare magnitudes of association of BMI and measures of regional adiposity with coronary heart disease, diabetes and all-cause mortality.

**Design:** 2 prospective cohort and 2 cross sectional studies.

**Participants:** Members of 4 UK cohorts aged ≥45 years: 3937 women from the British Women’s Heart and Health Study (BWHHS), 2376 and 1950 men from phases 1 and 3 of the Caerphilly Prospective Study (CaPS), 405 men and women from Boyd Orr, 789 men and women from Maidstone and Dewsbury (MD) study.

**Main Outcome Measures:** Incident all cause mortality, coronary heart disease (CHD) and diabetes (in CaPS and BWHHS), cross sectional measures of arterial plaques (in Boyd Orr and MD), blood lipids, blood pressure (in all 4 cohorts) and fasting glucose and insulin (in BWHHS, phase 1 CaPS and Boyd Orr).

**Results:** In BWHHS women, all measures of adiposity were strongly positively associated with incident diabetes, the strongest relationships seen with waist circumference (WC) (HR 2.35, 95% CI 2.05 to 2.73) and waist: height ratio (WHR) (HR 2.29, 95% CI 1.98 to 2.66). There was statistical evidence that both of these were more strongly associated with diabetes than BMI (HR 1.80 (95% CI 1.59 to 2.04) (p for heterogeneity both <0.02). In phase 3 CaPS men, there was no strong evidence for differences in the strengths of association with incident diabetes between BMI and WC, waist: hip ratio (WHR) and WHR (p all >0.49). Pooling estimates from BWHHS and CaPS revealed no evidence for differences in strengths of associations between BMI, WC, WHR or WHR and CHD. All cause mortality was associated with WC, WHR and WHR (HRs: 1.07 to 1.11) but not with BMI (HR 0.95) in pooled estimates (BWHHS, CaPS). Pooling odds ratios (Boyd Orr, MD) revealed no strong evidence for differences between anthropometric measures in their associations with arterial plaques. There was little evidence of differences between associations of BMI and other measures of adiposity with blood lipids, blood pressure, glucose or insulin in any of the cohorts.

**Conclusions:** Measurements of central adiposity (WC, WHR) were more strongly associated with diabetes than BMI in women but not men. There was no strong evidence for measurements of central adiposity being more strongly associated with CHD and stronger associations with all cause mortality were small. Further studies are required to determine whether measuring central adiposity in clinical practice would improve prediction of diabetes risk.

**054 ASSOCIATION OF BODY MASS INDEX, WAIST CIRCUMFERENCE AND WAIST-HIP RATIO WITH MORTALITY IN THE SCOTTISH HEALTH SURVEYS**

JW Hotchkiss, AH Leyland. MRC Social and Public Health Sciences Unit, Glasgow, UK
doi:10.1136/jech.2009.096727b

**Background:** Obesity is a major health challenge of the 21st century. Simple anthropometric measurements, including body mass index (BMI), waist circumference (WC) and waist-hip ratio (WHR), are utilised in epidemiological studies to capture (indirectly) summary estimates of body fat proportion. Some representative population surveys have not demonstrated the strong U or J shaped association between BMI and mortality that might be expected.

**Objectives:** To examine association of body size with mortality using BMI and two gender specific alternatives believed to reflect fat distribution: WC and WHR.

**Design:** The linked Scottish Health Surveys provide representative population data, collected by stratified and clustered probability sampling, and are linked to subsequent death records.

**Participants:** 22 426 respondents from three survey waves (1995, 1998 and 2003) who consented to data linkage and were between the ages of 18 and 86 years at the time of interview (9924 men, 12 502 women).

**Main Outcome Measures:** All-cause and cardiovascular mortality.

**Methods:** Cox proportional hazards analyses were used to model the relationship between mortality and each of the variables BMI, WC and WHR. Only valid measurements of each were included and each was divided into four categories with the second lowest category (38.4%, 40.5% and 49.5% respectively) as referent. Hazard ratios (HR) for survival time from interview to death, or 31 December 2007, were firstly adjusted for age, gender, smoking status, alcohol consumption and survey year; and then further adjusted by measures of socio-economic status. Sensitivity analyses involved stratification by gender and age.

**Results:** The prevalence of obesity, according to World Health Organisation definitions BMI (≥30 kg/m²), WC (men ≥102 cm, women ≥88 cm) and WHR (men ≥1.0, women ≥0.85) was 22.2%, 27.2% and 18.7% respectively. There was no increased risk of mortality associated with obesity as defined using BMI (HR 0.93, 95% CI 0.80 to 1.07). In contrast, the HR for subjects with obesity determined by WC was 1.17 (1.02 to 1.34) and by WHR was 1.54 (1.16 to 1.55). BMI and WC identified the association of “underweight” with increased mortality. Results for CVD mortality showed a stronger gradient. Inclusion of socio-economic status in the models attenuated the results to a limited extent. Gender stratification strengthened the association of underweight with mortality for men using BMI (HR 2.90; 1.87 to 4.51) and of obesity with mortality for women using WHR (HR 1.47; 1.19 to 1.83).

**Conclusions:** BMI may not capture the harmful association of body size with mortality. WC and WHR may more clearly define the health risks associated with excess body fat accumulation.

**055 ELEVATED BODY MASS INDEX IN EARLY ADULTHOOD AS A PREDICTOR OF LATER CORONARY HEART DISEASE MORTALITY: UP TO 82 YEARS FOLLOW-UP IN THE HARVARD ALUMNI HEALTH STUDY**

1GD Batty, 1L Gray, 2HD Sesso, 2M Lee. 1Medical Research Council Social and Public Health Sciences Unit, Glasgow, UK; 2Harvard School of Public Health, Boston, MA, USA; 3Brigham and Women’s Hospital, and Harvard Medical School, Boston, MA, USA
doi:10.1136/jech.2009.096727c

**Objectives:** Few studies have examined the association between adiposity in early adulthood and later coronary heart disease (CHD). Further, whether the impact of early adiposity is mediated via adiposity in middle age or, if it exerts an independent effect, has yet to be tested. We examined these issues using extended follow-up of the Harvard Alumni Study.

**Design:** Cohort study of male University students who had a physical examination at college entry between 1914 and 1952 (mean age 18.4 years) when data on CHD risk factors including body mass index (BMI; weight, kg/height, m²), our measure of...
adiposity, were measured directly. Study participants were traced, mailed a health questionnaire in 1962/1966 (mean age 45.1 years) which included enquiries regarding self-reported height and weight, and were followed for subsequent mortality experience – with > 99% completion – until the end of 1998. BMI was categorised into quintiles in the present analyses.

Setting: USA.

Participants: 14 638 men enrolled in Harvard University in the given years, who completed the subsequent health questionnaire, and whose vital status could be ascertained.

Main Outcome Measure: CHD death.

Results: Over a maximum of 82.5 years of follow-up (median 56.5 years), there were 1401 deaths from CHD. Following adjustment for age and other CHD risk factors (cigarette smoking, physical activity, blood pressure) at college entry, relative to the lowest weight quintile (mean BMI = 18.7 kg/m²), there was an elevated risk of CHD mortality in men in the highest quintile (mean BMI = 25.0 kg/m²; hazards ratio 1.28, 95% CI 1.10 to 1.49) but not the intermediate groups. Following additional control for BMI in middle-age, this increased CHD risk in the highest quintile was eliminated (1.05; 0.87 to 1.21).

Conclusion: In this cohort, higher BMI in early adulthood was associated with an elevated risk of CHD mortality several decades later but this effect appeared to be entirely mediated via BMI in middle-age.

056 THE LONG TERM EFFECTS OF CHILDBEARING AND BREASTFEEDING ON BODY MASS INDEX IN MIDDLE AGED WOMEN RESULTS FROM THE MILLION WOMEN STUDY

1K Bobrow, 1M Quigley, 1J Green, 1G Reeves, 1V Beral, on behalf of the Million Women Study Collaborators; 1Department of Public Health, University of Oxford, Oxford, UK; 2National Perinatal Epidemiology Unit, University of Oxford, Oxford, UK; 3Cancer Epidemiology Unit, University of Oxford, Oxford, UK.

doi:10.1136/jech.2009.096727d

Objectives: To examine the relation between childbearing and breastfeeding and subsequent body mass index (BMI) in middle-aged women.

Design: Cross-sectional analysis within a large prospective study.

Participants: One million UK women recruited into the Million Women Study during 1996–2001. Participants completed questionnaires collecting information on personal and lifestyle characteristics, medical and reproductive history including questions on childbearing and breastfeeding, anthropometry, physical activity, and socio-demographic factors.

Main Outcome Measures: Mean BMI stratified by parity and breastfeeding and adjusted for age, geographical region, socio-economic status, smoking status, strenuous physical activity, age at first birth, and years since last birth.

Results: 980 474 women were included in the main analysis. 87% of the study population were parous, mean parity was 2.1 (1.2) and 68% of parous women ever breastfed. The mean lifetime duration of breastfeeding per child was 3.8 (SD 3) months. Mean BMI increased significantly with each birth from 25.8 (95% CI 25.7 to 25.8) for nullips to 28.1 (95% CI 28.1 to 28.3) for women with five or more births. Parous women who breastfed had significantly lower BMIs than their non-breastfeeding counterparts. The effect was attenuated by adjusting for BMI in middle-age, this increased CHD risk in the highest quintile was eliminated (1.05; 0.87 to 1.21).

Conclusion: In this cohort, higher BMI in early adulthood was associated with an elevated risk of CHD mortality several decades later but this effect appeared to be entirely mediated via BMI in middle-age.

057 EXPLAINING THE MENTAL HEALTH ADVANTAGE OF BRITISH INDIAN CHILDREN

A Goodman, V Patel, O Leon. Department of Epidemiology and Population Health, London School of Hygiene and Tropical Medicine, London, UK.

doi:10.1136/jech.2009.096727a

Objective: To investigate the causes of the lower rate of mental disorders diagnosed in British Indian children compared to White children.

Setting: Great Britain (nationally-representative sample). Mental health outcome measures: Parent Strengths and Difficulties Questionnaire (SDQ); teacher SDQ; child SDQ; multi-informant clinical diagnosis.

Participants: 16 449 White and 419 Indian children aged 5–16. The detailed multivariable models focused on the 13 602 White and 361 Indian children from England whose parents had completed an SDQ in English.

Results: There was a substantially lower prevalence (p<0.001) of any mental disorder in Indians (3.4%, 95% CI 1.9 to 5.9) compared to Whites (9.6%, 95% CI 9.1 to 10.2). Strong evidence (p<0.002) of an Indian advantage for externalising problems/disorders was consistently observed for the parent, teacher, child SDQs and for clinical diagnosis. Detailed psychometric analyses of the SDQ and clinical interview measures provided no evidence that this Indian mental health advantage could be explained by a measurement bias in the assessment of mental health. In multivariable analyses the unexplained difference between Indians and Whites decreased somewhat after adjusting for the fact that Indian children were more likely to live in two-parent families (92.2% vs. 65.4%) and less likely to have academic difficulties (e.g. 2.9% vs. 8.6% for parent-reported learning difficulties). In models adjusting for a larger number of child, family, school and area variables the difference reduced only by about a quarter (e.g. from 1.08 to 0.75 SDQ points on the parent SDQ) and remained highly significant (p<0.001). There was little or no evidence of an ethnic difference for internalising problems/disorders in unadjusted or adjusted models.

Conclusions: The mental health difference between Indian and White children is specific to a substantial advantage for externalising disorders, and this advantage appears to be real rather than due to a reporting bias. This advantage is largely unexplained by major risk factors for child mental health problems available in this dataset. Further qualitative and quantitative research into the causes of this advantage has the potential to yield insights which could improve the mental health of children of all ethnic groups.

058 EMERGENCE OF ETHNIC DIFFERENCES IN BLOOD PRESSURE IN ADOLESCENCE: THE DETERMINANTS OF ADOLESCENT SOCIAL WELL-BEING AND HEALTH LONGITUDINAL STUDY

1E Lenguerrand, 1S Harding, 1M Whitrow, 1M Maynard, 1K Cruickshank, 1G Der, 1A Teyhan. Medical Research Council, Social and Public Health Sciences Unit, University of Glasgow, Glasgow, UK; 2Division of Cardiovascular and Endocrine Sciences, University of Manchester, Manchester, UK.

doi:10.1136/jech.2009.096727f

Objective: To examine ethnic differences in changes in Blood Pressure (BP) between early and late adolescence in the UK.
Elevated body mass index in early adulthood as a predictor of later coronary heart disease mortality: up to 82 years follow-up in the Harvard Alumni Health Study
