**EXPOSURE TO TRAFFIC AND CANCER HOSPITALISATION IN São Paulo**  
doi:10.1136/jech.2011.142976j.87

A Ribeiro,* A Nardocci. University of São Paulo, São Paulo, Brazil

**Introduction**  
Previous studies in developed countries have documented associations between air pollution and risk of some neoplasms. We explored the association of traffic-related air pollution with hospitalisations for cancer groups.

**Methods**  
Our analysis included all individuals admitted to public or private hospitals in São Paulo from 2004 to 2006 with a main diagnosis of primary invasive cancer. Only the first individual admission was considered, from which age, sex, diagnosis and home address were extracted. We calculated total, gasoline and diesel vehicles traffic density, from traffic counts data, for 496 geographical units with a population of 20 or more inhabitants, formed by a grid of 500 by 500 m. We used logistic regression models adjusted by the Human Development Index of the area for groups of cancer.

**Results**  
There was an increased risk of hospitalisation for respiratory neoplasms in adults and for haematologic neoplasms in children and adolescents associated with living in areas with higher total traffic density and traffic density for vehicles powered by gasoline and diesel, with a clear dose-response gradient. The Rate ratios of these neoplasms for the highest category of exposure to total density traffic were, respectively, 3.5 (95% CI 2.26 to 4.87) and 2.5 (95% CI 1.59 to 3.49).

**Conclusion**  
Our study suggests an association between traffic air pollution and hospital admissions for respiratory and haematologic cancers. The adjustment for potential confounding variables, the use of more sophisticated exposure assessment models and of incidence data are needed to more directly investigate the cause and effect relationship.

**TRENDS IN MORTALITY DUE TO POTENTIALLY HPV-RELATED HEAD AND NECK CANCERS IN BRAZIL, 1980–2007**  
doi:10.1136/jech.2011.142976j.88

**Introduction**  
Alcohol and tobacco are the most important risk factors for head and neck cancers (HNC). However, in some countries, it has been observed an increase in incidence rates, particularly among young people and among non-drinkers and non-smokers. These trends have increased the debate about the role of human papilomavirus (HPV) and several studies suggest that this infection may play a causative role in oropharyngeal tumours. This study aims to assess the magnitude of cancers potentially related to HPV in Brazil.

**Methods**  
Time series study including deaths due to HNC registered in Brazil, from 1980 to 2007. Age-adjusted mortality rates are described for 100 000 people, according to tumour site (HPV-related or non-HPV related) and sex. Annual percentage change (APC) was calculated through Joinpoint modeling method, using the calendar year as regressor variable.

**Results**  
We observed a statistically significant increasing trends in mortality rates due to HPV-related HNC among males in the periods of 1980–1994 (APC=2.4, 95% CI 1.0 to 3.8) and 1997–2005 (APC=4.0, 95% CI 0.8 to 7.4), followed by a decrease in 2005–2007 (APC=−27.2, 95% CI −44.6 to −4.4), while for females a significant increase in rates was observed between 1980 and 1998 (APC=7.6, 95% CI 0.3 to 15.4), followed by a decreasing trend in the period 1998–2007 (APC=−2.7, 95% CI −4.2 to −1.3). Regarding non-HPV related HNC, significant changes were only observed for females (1980–2007, APC=−2.1, 95% CI −2.8 to −1.4).

**Conclusion**  
Important increases in HPV-related HNC mortality were recently observed in Brazil, particularly among females. These results can suggest that these trends reflects better prognosis related to HPV-positive HNC.

**DESCRIPTIVE DATA ON WORK-RELATED CANCER IN BRAZIL: AN ANALYSIS WITH COMPENSATION BENEFITS**  
doi:10.1136/jech.2011.142976j.89

1 F Ribeiro,* 2 V Santana, 3 W Souza. 1Rio de Janeiro State University and National Cancer Institute, Rio de Janeiro, Rio de Janeiro, Brazil; 2Institute of Collective Health, Federal University of Bahia, Salvador, Bahia, Brazil; 3University of Brasilia, Brasilia, Distrito Federal, Brazil

In Brazil, data on work-related diseases and injuries are commonly recorded by the Brazilian Social Security Institute, INSS, which covered 32% of the economically active population, approximately 32 million workers, in 2009. Industries known to be associated with potential exposure of workers to carcinogenic substances are spread throughout the country and account for a substantial proportion of the labour force. There are no published work-related cancer statistics. This study describes the national distribution of occupational cancer cases leading to compensation benefit in Brazil, from 2000 and 2007.

**Methods**  
The study population comprised of all insured workers eligible for work-related compensation benefits, recorded electronically in the INSS. Cases were workers who received a compensation benefit classified as work-related and ICD-10 (C30–C39). Descriptive variables were sex, age, income, state, industry trades and year of the benefit.

**Results**  
The number of registered benefits for cancer cases increased from 33 488 to 43 464; from these 724 (0.4%) work-related cancer cases were found. Most were <35 years of age and from the first income quartile. Cases were more likely to come from the construction industry, and leukaemia and other haematopoietic cancers predominated. The number of reported work-related cases declined from 100 in 2000 to 34 in 2006, when they started to increase reaching 266 in 2007.

**Conclusions**  
In Brazil, the number of reported cases of work-related cancers was small and decreasing during the last decade. After the implementation of a distinct work-relatedness protocol in 2007 it changed, increasing over 100%, suggesting large under reporting. Epidemiological estimates with these data are presently undergoing.

**SOCIAL DETERMINANTS AND HIGH RISK BEHAVIOURS IN DRUG USERS UNDER METHADONE TREATMENT IN GOLESTAN PROVINCE, NORTH IRAN**  
doi:10.1136/jech.2011.142976j.90

1 M Gholi-pour, 2 A Keshtkar, 3 R Majdadeh, 4 A Badakhshan, 5 S neji, 1 M Qorbani, 1 M Vakili, 2 H Salari. 1Community Medicine Department, School of Medicine, Golestan University of Medical Sciences, Gorgan, Golestan, Iran; 2Endocrinology Metabolism Research Centre, Tehran University of Medical Sciences, Tehran, Iran; 3Epidemiology and Biostatistics Department, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran; 4Deputy of treatment, Golestan University of Medical Sciences, Gorgan, Iran; 5Kazeroon university of Medical Sciences, Tehran, Iran; 6Psychiatric Department, School of Medicine, Golestan University of Medical Sciences, Gorgan, Golestan, Iran

**Introduction**  
Drug users’ health is a product of drug-effects and risk behaviours. Social determinants can shape some health behaviours. There has been little research on social determinants and risk behaviours related to drug use in Iran. We aimed to estimate this in patients undergoing methadone treatment in north Iran.
Methods 400 addicts were recruited from methadone clinics in 2009–2010. A self-designed questionnaire with excellent reliability was used to determine those with and without high risk behaviours. ORs with 95% CIs were estimated by logistic regression. Ethics approval was obtained from Tehran University.

Results There was significant difference between the two study groups (with and without high risk behaviours) in economic status, drug type, administration route, age, and drug abuse onset age. Education level was significantly lower in women. One quarter experienced homeless, 62% had no support from any insurance or supportive organisations, only 26% had constant employment and over 50% had prison history. 12.5% were injection users and 14% shared syringes. One quarter reported high risk sexual behaviour and 69.4% had not used condoms in last their last sex encounter (significantly lower in women). A decrease of one year in age was associated with decreased drug use onset age and increased sexual risk behaviours by 6% (AOR = 0.94, 95% CI 0.91 to 0.98) and 10% (AOR = 0.91, 95% CI 0.85 to 0.97) respectively. Poor economic status reduced risk sexual behaviour (AOR = 0.55, 95% CI 0.15 to 0.96). Prison history increased injection behaviour more than twice (AOR = 2.89, 95% CI 1.4 to 5.95).

Conclusions These findings illustrate that interventions are needed in young heroin users even in those with a good economic status.

P2-259 CANCER RISK IN CHILDREN WITH BIRTH DEFECTS: A LONGITUDINAL, POPULATION-BASED ASSESSMENT AMONG 2.7 MILLION BIRTHS
doi:10.1136/jech.2011.142976j.92
1P A Romiti,* 2T Flood, 3M L Feldkamp, 5S Krikov, 6S Puzhankara, 7R Goedken, 3M Fuchel, 7J Little, 4L D Botto. 1The University of Iowa, Iowa City, Iowa, USA; 2Arizona Department of Public Health, Phoenix, Arizona, USA; 3University of Utah, Salt Lake City, Utah, USA; 4University of Ottawa, Ottawa, Ontario, Canada

Introduction The published literature, to date, is largely inconclusive regarding cancer risk among children with birth defects. To improve knowledge of such risk, we studied population-based ( statewide) birth cohorts from Arizona, Iowa, and Utah selected from among 2.7 million births delivered from 1983 to 2006.

Methods Birth defect and cancer diagnoses were identified from linked population-based surveillance systems. A population-based cohort of over 43 000 children with major birth defects (including trisomies 15, 18, and 21) was compared to a cohort of nearly 148 000 births without birth defects, randomly sampled from the same underlying birth population and frequency-matched to the birth defects cohort by birth year. Kaplan-Meier time-to-event analysis, accounting for censoring by death, was used to estimate cancer risk up to age 15 years.

Results Compared to the reference cohort, children with birth defects had a statistically significant increase in cancer risk (RR, 2.75). Risk was highest among children with Down syndrome (RR, 15.2), and was driven largely by leukemias. Cancer risk was moderately increased among children with a birth defect but without chromosomal anomalies (RR, 1.82). In this group, cancer risk was driven largely by brain tumours and embryonal tumours, and occurred mainly in children with brain defects, cleft palate, rectal defects, and some heart defects.

Conclusion These population-based findings support and extend previous findings that suggest increased cancer risk in children with birth defects, including non-chromosomal defects, and suggest selected defect groups in which further research could help identify a common genetic susceptibility to cancer and birth defects.
