positive linear relationship between adherence and cessation rates however, adherence to NRT among unmotivated smokers is uncertain.

**Methods**

Chinese smokers who aged ≥18, had no intention to quit within 4-week and had no contraindication to NRT were recruited and randomly allocated to Group A1, A2 and B in a RCT. Only Group A1 and A2 were provided 8-week free NRT. We reported 8-week adherence rate to NRT at 3-month and reasons for non-compliance among subjects in Group A1 and A2.

**Results**

From October 2004 to April 2007, 1154 smokers were recruited (Group A1 = 479, A2 = 449, B = 226). Subjects in Group A1 and A2 (n = 928) were 42.0±10.3 years-old and smoked 19.6±9.4 cigarettes daily on average. We contacted 797 subjects (85.9%) for 3-month follow-up, but those who did not receive 8-week free NRT (n = 115, 14.4%) were removed from the analysis. 35.4% (575/1628) used NRT as the recommended regime, 41.6% (284/682) did not fully comply with the prescription and 3.0% (20/682) even did not use it. Among 304 (n = 284+20) who did not comply, "Forget to use" (24.0%) and "Side effects" (14.5%) are the two most cited reasons for non-compliance.

**Conclusion**

The adherence rate in this study is more encouraging compared to a local study (20%) which only provided 1-week free NRT. Thus, providing the entire course of free NRT seems to yield an improved NRT adherence among unmotivated Chinese smokers.

**SOCIAL POSITION AND RISK OF DEMENTIA IN PEOPLE WITH HIGH LEVELS OF ABSOLUTE POVERTY BUT LOW LEVELS OF CARDIOVASCULAR RISK FACTORS AND DEPRESSION: THE ANHUI COHORT STUDY**

doi:10.1136/jech.2011.142976p.17

1R Chen,* 1University of Wolverhampton, Wolverhampton, UK; 2Anhui Medical University, Hefei, China

**Introduction**

The relationship between dementia and socioeconomic deprivation is unclear. This study examined the association between social position and dementia, and determined the prevalence of dementia diagnosed using the 10/66 algorithms in people with high levels of absolute poverty but low levels of cardiovascular risk factors and depression.

**Methods**

Prospective cohort study of 1766 elders in rural and urban community-dwellings in Anhui, China. Standardised mental status measures were administered and socioeconomic and risk factors were characterised at baseline. At 6.2-year follow-up, dementia cases were identified using the 10/66 algorithms, causes of death and reports by psychiatrists.

**Results**

The world age-standardised prevalence of dementia diagnosed by the 10/66 algorithms was 5.41% (95% CI (4.26% to 6.55%)); in men 4.38% (2.88% to 5.89%) and in women 6.44% (4.76% to 8.13%). The risk of dementia significantly and independently increased with age, lower educational level, uncontrolled hypertension, not watching television, feeling lonely and hearing problems. Compared to those that achieved an educational level of ≥ secondary school and middle income participants, those with lower educational attainment and in the lowest or highest income groups had a higher risk of dementia; multiple adjusted OR (AOR) were 2.99 (1.24 to 7.25) and 3.00 (1.09 to 9.97) respectively. Business/non-labouring participants with educational levels of ≤ primary school had the highest risk of dementia (AOR 3.80 (1.43 to 10.11) compared to other combinations of occupational class and educational level.

**Conclusions**

Increasing income and minimising the gap in income between poor and rich may reduce the epidemic of dementia in China. Increasing levels of education and TV watching could be an efficient measures to prevent dementia in developing countries.
Results Semen assessments were obtained for 502 men. This group was representative of the general population regarding social class, education and geography. The median sperm concentration of samples was $48 \times 10^6$/ml, but after adjustment to a mean abstinence of 4 days, $64 \times 10^6$/ml. In these adjusted data, "low" sperm counts (below $20 \times 10^6$/ml) were found in 18% of men (95% CI 15% to 21%). However, the prevalence of "low" sperm counts showed no trend across the 10-year range of birth years.

Conclusion This first report of sperm concentration in a random sample of a general population shows that nearly a fifth of men had poor semen quality. Further work is required to clarify the fertility relevance of a single low sperm concentration when there is no imposition of abstinence prior to sample, and to understand cause of the fertility deficit found in many survey participants.

Background Environmental toxic metal exposure may adversely affect children’s development and behaviour. Data are lacking about heavy metal exposure in children in UAE and Gulf countries.

Objectives To determine blood concentrations of 12 heavy metals in school-age children in Al Ain City, UAE.

Methods It was a cross sectional study. One hundred and forty seven subjects were selected from nine elementary schools. The mean age was 8.4 years (SD ±2 years). ICP-MS instrument was used to determine the metal concentration. Data analysis was performed using the SPSS.

Results The (mean±SD) blood level for study children (n=146) of lead was 25.86±13.06 ppb, cadmium 0.51±0.25 ppb, arsenic 10.74±4.71 ppb, mercury 1.39±1.16 ppb, manganese 1.85±1.09 ppb, nickel 9.18±8.23 ppb, zinc 3751±1752 ppb, chromium 2.10±1.53 ppb, cobalt 0.65±0.40 ppb, copper 1064±403 ppb, molybdenum 1.59±1.25 ppb, and antimony 0.60±0.65 ppb.

Conclusions Reference values for the trace metals vary markedly; especially due to sampling, age, diet, exposure differences and analytical techniques used. In this study, the mean blood lead was below the CDC’s recommended level of concern (>10 µg/dl) and with cadmium, mercury and chromium were comparable with similar studies elsewhere; manganese and zinc were slightly lower; copper and molybdenum were slightly higher while arsenic and cobalt much higher. Blood screening and surveillance linked to appropriate public health interventions is strongly recommended for UAE.

Introduction Several studies have shown that many aquatic ecosystems are often contaminated with pathogenic microorganisms through the discharge of untreated or partially treated sewage. The maintenance of water quality is a major challenge for governments with direct consequences on the health of the environment and the population. Mangrove is an important source of livelihood for fishermen living in the region of Vitória, ES, Brazil. In the last years high numbers of gastroenteritis cases have been reported in this region suggesting an association between the consumption or handling of contaminated water and mussels and the development of gastrointestinal diseases. The aim of this study was to investigate the sanitary quality of water and mussels and to evaluate an association of gastroenteritis cases and the presence of adenovirus and bacterial indicators of fecal pollution in these samples.

Methods Feces of children from 0 months to 12 years living in the areas of study and diagnosed with gastroenteritis are collected and evaluated for the presence of adenovirus. Water and mussels are sampled monthly and analysed for adenovirus by PCR and nested-PCR; total coliforms and E. coli were detected using the Total Coliform/E. coli Enzyme substrate test (Colilert ®).

Results All water samples and mussels analysed were positive for E. coli. Adenovirus genome was detected in 76% of water samples and 100% of mussel samples collected.

Conclusion These data shows that this area is highly contaminated with domestic sewage and indicates that consumption of seafood may be associated with cases of gastroenteritis reported in the region.
SP4-25 Population survey of semen quality in young Scottish men
