Analysis of ethnic influence on stillbirths and infant mortality in Bradford 1975–81

DOUGLAS R N GILLIES, GEOFFREY T LEALMAN, KATHLEEN M LUMB, AND PETER CONGDON

From the Ethnic Minorities Health Studies Centre, Bradford Royal Infirmary, Bradford 8, UK

SUMMARY The patterns of mortality from birth to 1 year in Bradford were studied in the seven year period 1975–81. Large differences in mortality between the Asian and non-Asian population were shown. In 1981 77% of Bradford Asian families were of Pakistani origin, the remaining 23% consisting of families from other parts of the Indian subcontinent and a few from East Africa. There was excess mortality with associated congenital abnormality in the Asian population. From 1975 to 1981 there were 133 deaths associated with congenital abnormality (a rate of 12.4 per 1000 total births) in the Asian population compared with a figure of 129 (4.8 per 1000) in the non-Asian population. The differences between the two groups are shown to be largely independent of social class, and other possible reasons for the discrepancy between the Asian and non-Asian populations are discussed.

Asian births in Bradford rose from 22% of the total births in 1975 to 30.5% in 1981. This retrospective study examines the stillbirth and infant mortality rates in Bradford and compares the Asian with the non-Asian community. Considerable differences in mortality rates are shown and reasons to account for this are discussed. In addition deaths with associated congenital abnormality are examined in more detail.

Methods

Unlike some other hospital based studies^{1,2} these data are derived from all births and infant deaths occurring within a health district. In Bradford 99% of births take place in the city's two maternity units. Basic data such as maternal parity and infant weight are stored on computer and are easily retrievable, but we obtained more detailed information from maternal and neonatal notes, hospital and coroners' necropsies, and death certificates. In addition stillbirths and neonatal deaths are discussed at bimonthly perinatal mortality meetings.

Mortality patterns were looked at in three groups:

- Stillbirths.
- Early neonatal deaths at under 1 week.
- Infant deaths from 1 week to 1 year.

Rates and patterns of congenital abnormality were also studied within these three groups.

Results

Table 1 shows the consistently higher level of mortality in the Asian population that is reflected in the increased stillbirth rate and persists till the end of the first year. Mortality rates tended to drop in both groups over the seven year study period, but even in 1981 the perinatal mortality rate for the Asian community was double that for the Caucasian community at 20.8/1000 total births.

To see whether congenital abnormality contributed to these differing rates, patterns of congenital abnormality were analysed and are shown in table 2. The years 1975–81 are grouped together as numbers are otherwise inadequate. Analysis showed similar patterns each year to that shown overall. Congenital abnormality is a serious problem in the Asian population, being twice as common in stillbirths at 4.6/1000 total births as against 2.1/1000 total births for non-Asians. The high mortality due to congenital abnormality persists throughout the first year. By the end of the first year deaths from congenital abnormality account for 12.8/1000 total births in Asians (133 babies) and 4.8/1000 total births in non-Asians (129 babies) ($p < 0.0001$).

The Pakistani community is the predominant Asian group in Bradford and had 74% of all deaths associated with congenital abnormality that we were able to analyse (table 3). In 11% of Asian deaths we

were unable to classify the Asian subgroup. Therefore, most observations made regarding the Bradford Asians apply to the Pakistani population which suffers severe social disadvantages when compared with the non-Asian population.³

To compensate for this social class difference table 4 shows class specific death rates. The analysis was made for the years 1979–81 as earlier data were not available. It is striking that in social classes IV and V deaths associated with congenital abnormality are significantly greater ($p < 0.01$) at 20.0/1000 total births in the Asian population. Deaths not associated with congenital abnormality showed similar rates in both groups.

Discussion

Rates for stillbirths and deaths under the age of 1

year were throughout higher in the Asian population. These high mortality rates have been seen in previous studies of immigrant groups, but this paper illustrates the large burden of congenital abnormality borne by the Asian population in this area. With regard to stillbirths, malformations of the central nervous system are the most common congenital abnormality in both groups but the incidence of this in the Asian population, 3.3/1000 total births (35 babies), is almost double that in the non-Asian population (1.4/1000). Nevertheless, all types of congenital abnormality are more common in the Asian population, and in particular we show that multiple congenital abnormality is much more frequent with many of the patterns of abnormality being unrecognisable as specific syndromes. Although many congenital abnormalities are lethal either at birth or within one week of birth, there remains a high level of deaths associated with congenital abnormality in the period 1 week to 1 year. During this period 35% of deaths in the Asian population (41 babies) are associated with congenital abnormality as compared with 22% in the non-Asian population (44 babies).

Several factors might be operating in the Asian community to produce the high of mortality and

congenital abnormality. Perinatal mortality is closely linked to social class.⁴ In the years 1979–81 inclusive 70% of Asian mothers came from social classes IV and V compared with 23.2% of non-Asians. Other associated factors favouring high mortality rates in the Asian population are low maternal height, poor antenatal attendance, generally lower concentrations of haemoglobin during pregnancy, the high parity of Asian mothers, the practice of child bearing till late in life, and the high numbers of low birthweight babies.³ The effect of two of these factors, parity and age, is shown in tables 5 and 6.

In both communities death with associated congenital abnormality is closely related to social class. Social class specific mortality rates, however, show that the Asian population has excessive rates of death associated with congenital abnormality when compared with similar social class groups in the non-Asian population. As recent studies have suggested that periconceptual vitamin status could be concerned in the genesis of neural tube defects,⁵ this

might be particularly important in the Asian population. Consanguinity might influence levels of abnormality. In 1981 midwives in Bradford analysed marriages and found that 48% of Pakistani marriages were between first cousins compared with 8% of Indian marriages and 0.5% of non-Asians. In addition the generally higher parity of Asian mothers and their practice of child bearing till late in life may have a bearing on the incidence of congenital abnormality.

It seems unlikely that the social class structure of the Asian population will change in the immediate future, and the reduction of high levels of mortality and morbidity will depend on the use of simple intervention measures, such as vitamin supplementation of the Asian mother during pregnancy. Asian families should know that genetic screening and counselling are readily available. In a London based study 60% of Asian families at risk requested antenatal diagnosis for thalassaemia.⁶ This interest may extend to termination of affected

fetuses, but such a service would have to be offered in the highest confidence.

Many non-Asian women find antenatal clinics overcrowded and impersonal, and this is likely to be worse for Asian mothers where communication difficulties are common. The greater provision of interpreters and other Asian health workers could ensure higher levels of attendance, fewer communication difficulties, and produce practical suggestions for improving antenatal facilities for Asian families.

A recent study has highlighted some of these problems of the Asian population with regard to antenatal care.⁷ Suggestions for improving both poor antenatal attendance and standards of antenatal care were made, but a real improvement in perinatal outcome will probably take place only when the Asian community can be helped to accept and use the existing medical facilities. This could perhaps be best achieved by concentrating resources on health education within schools.

We thank Sandra Haigh for undertaking the statistical analysis.
