Screening for ischaemic heart disease risk factors at a health fair: low attendance by those at highest risk

M WATTS¹* AND I S JOHNSON²†

From ¹Sheffield Health Authority and ²Trent Regional Health Authority.

ABSTRACT Among people attending a heart disease screening project at a Health Fair in Sheffield, only 22 of 425 (5.2%) lived in areas with more than 25% of the population belonging to social classes IV or V. The incidence of heart disease is known to be particularly high in these areas, where 15.1% of the total population live. By analysis of the attendance rates from districts other than those immediately adjacent to the site of the Health Fair, we found that the strength of this inverse correlation increased, suggesting that the problems of access are probably greater for people living in deprived areas than for others.

Despite the fact that multiple risk factor intervention applied on a mass basis during adult life has not yet been shown convincingly to be of benefit in preventing ischaemic heart disease,^{1–4} many still argue that strategies aimed at changing the health related behaviour of the community as a whole are the best approach to reducing the incidence of this condition.^{5–9} A mass screening initiative for ischaemic heart disease was undertaken at the Sheffield Health Fair in June 1985.

This Fair was arranged to coincide with the Health Education Council's 2000 mile "Great British Fun Run" which, together with locally organised events (such as the Sheffield Health Fair), aimed to raise public awareness of the value of health and exercise.

In Sheffield the Fair was coordinated by the Health Education Unit with financial backing of £10 000 from the District Health Authority. A variety of activities were organised including cooking for a healthy diet, fitness testing and exercise instruction, gymnastic displays and information on local self help and community groups such as "Drug Line". Opportunities for cervical cancer and ischaemic heart disease risk factor screening were provided by Health Authority staff. Analysis of the characteristics of people who took advantage of this opportunity to be screened for heart disease risk factors is the basis for this paper.

Methods

Screening for ischaemic heart disease risk factors was conducted in two adjacent marquees by volunteers recruited from Health Authority staff. In the first marquee, height and weight were checked by a nurse and a questionnaire about health related behaviour completed. In the second, blood pressure was measured by a doctor and, after noting the responses on the questionnaire, appropriate advice was given or action taken. Details were recorded on a printed form, a copy of which was sent to the person's general practitioner. The Fair was publicised in the local newspaper and on the local radio. Posters were placed on the perimeter fence of the venue. The population and social class composition of Sheffield postal districts were obtained from the 1981 OPCS census¹⁰ and mortality data for ischaemic heart disease from 1985 OPCS death tapes.¹¹ Here we record the results of an analysis of the area of residence of those people attending for screening with respect to the social class composition and known incidence of ischaemic heart disease in these areas, and the relationship of the distance from the site of the Health Fair.

Results

Five hundred and forty people participated in ischaemic heart disease risk factor screening over a two and a half day period. Of these, people under the age of 16 years, those living outside the Sheffield city boundary and those whose postcode was not noted were excluded, leaving 425 for analysis.

Screening for ischaemic heart disease risk factors

235

Attendance rates of the adult population were calculated by postal sector (table 1) and grouped into quintiles as shown in the figure. As expected, there was

Table 1 Health fair attendance rates by postal sector

Postal sector	Number attending (95% confidence intervals)	Attendance rate per 1000 resident adult population
S1	1 (0-3)	1.03
S2	11 (5-18)	0.28
S3	4 (0-8)	0.79
S4	2 (1-3)	0.19
S5	14 (7-21)	0.25
S6	43 (36-50)	0.80
S7	25 (15-35)	2.15
S8	35 (23-47)	0.77
S9	5 (1-9)	0.26
S10	36 (24-48)	2.34
S11	139 (116-162)	4.24
S12	19 (11-28)	0.53
S13	22 (13-31)	0.89
S14	6 (1-11)	0.64
S17	18 (10-26)	1.40
S19	7 (2-12)	0.51
S30	38 (26-50)	0.90

a tendency for the highest rates to be found in the districts nearest to the site of the Health Fair. More importantly, comparison of the attendance rates with the percentage of people belonging to social class IV or V in that postal sector showed there to be a significant inverse correlation ($r_s = -0.6021$, $p < 0.05$, $df = 16$, 2 tail), with the lowest attendance rates being found in the most deprived areas. When those districts immediately adjacent to the site of the Health Fair were excluded (ie, those with boundaries meeting that of "S11"), the negative correlation between social class and attendance rate became much stronger ($r_s = -0.8226$, $p < 0.01$, $df = 12$, 2 tail).

As shown in table 2, there was a significant correlation between death rates from IHD in the 25-64

Table 2 Mortality from ischaemic heart disease and social class by postal sector

Postal sector	Mortality rate from IHD per 1000 adults 25-64 years	% Social class IV and V
S1	3.62	30.1
S2	1.99	26.4
S3	2.40	27.1
S4	1.00	22.6
S5	2.26	24.0
S6	2.21	17.3
S7	2.33	12.0
S8	1.54	16.2
S9	1.45	20.4
S10	0.81	9.30
S11	0.73	8.90
S12	2.32	18.1
S13	1.92	18.3
S14	2.99	26.2
S17	1.35	5.10
S19	2.15	18.1
S30	1.76	14.1

IHD = ischaemic heart disease

years age group, and the percentage of social class IV or V in these districts ($r_s = 0.6119$, $p < 0.05$, $df = 16$, 2 tail), thus confirming the well known relationship between these variables.

Discussion

Opportunistic screening on a mass basis at a Health Fair is just one of the many possible ways of screening for ischaemic heart disease risk factors. In Sheffield the direct costs of the project were minimised by the use of volunteers, and the Health Fair offered health education benefits beyond the screening exercise. Nevertheless, the opportunity costs of such a venture are not inconsiderable and it is worth conjecturing whether the money invested by the District Health Authority was well spent, especially since other health education projects have been shown to receive most

attention from those who least need it.¹² In our study, only 87 (16%) of participants admitted smoking tobacco in some form, and 314 (58%) claimed to exercise briskly at least three times a week. Other studies have shown that about a third of the general population smoke and less than one fifth take regular brisk exercise.^{2 13-15}

Our study has shown that, in Sheffield, those people living in areas where the incidence of death from IHD is highest are less likely to participate in risk factor screening than those living in areas of lower incidence (who by implication are at lower risk).

We have also shown that when the analysis is confined to the residents of postal districts which are not immediately adjacent to that in which the event was held, there is an increase in the negative correlation between low social class and attendance rate. One possible explanation for this finding might be, as suggested by Wrench and Irvine,¹⁶ that access to the venue is a more important barrier to people of social classes IV and V than to others. In 1985 Sheffield had a highly subsidised public transport system with frequent buses charging a maximum fare of 20 pence. Thus if access is a major factor, then this will be a far more potent deterrent in most other areas with less favourable transport policies.

Part of the different attendance rates may have been due to unequal advertising coverage with city wide newspaper and radio announcements reaching a more selected audience than in the area of the event, where the message was reinforced by posters.

We conclude that the site of such events may be an important factor in determining their effectiveness. However, it could be argued that Health Fairs of this type are inherently less attractive to the people of social classes IV and V irrespective of the distance from the venue. As such they would yield a poor return on investment of scarce health promotion funds. Our findings would be equally consistent with such a view.
