Little or no work has been done on sociocultural beliefs and sexual activity of postmenopausal women in Nigeria. This study was carried out to assess socio-cultural beliefs and sexual activity among postmenopausal women in Ibadan NorthEast Local Government Area. A cross-sectional study was conducted among 522 postmenopausal women aged 40–65 years. An interviewer-administered questionnaire was used to collect data on sociodemographic characteristics, attitude to sociocultural beliefs regarding sexual activity and current sexual activity of respondents. Descriptive statistics and logistic regression were used for data analysis. The mean age of the respondents was 54.0±5.6 years. Overall, 45.7% agreed with at least one of the stated socio-cultural beliefs and the mean attitudinal score was 4.1±5.2. Among those who currently had partners, only 30.7% reported post-menopausal sexual activity. Significantly higher proportions of those with no formal education (78.6%), those aged ≥50 years (69.9%) and with supportive attitude towards the socio-cultural beliefs (83.8%) reported cessation of post-menopausal sexual activity (p<0.05). The significant predictors for cessation of post-menopausal sexual activity were no formal education (OR=4.1, 95% CI from 2.0 to 8.3), supportive attitude towards socio-cultural beliefs (OR=5.6, 95% CI from 3.4 to 9.4) and older age group (OR=4.1, 95% CI from 2.4 to 7.0). Socio-cultural beliefs affected post-menopausal sexual activity among these women; this may result in their partners seeking for alternative sexual partners with the attendant problems of sexually transmitted infections. There is need for the development of educational interventions targeted at changing these beliefs.

**Preoperative Body Mass and Risk of Complications After Hysterectomy on Benign Indications**

**Introduction** This study examines preoperative Body Mass Index (BMI) in relation to risk of complications after hysterectomy on benign indications, and explores whether any associations vary by route of surgery.

**Methods** A cohort study which includes data on health and lifestyle collected prospectively by the surgeon whenever a woman was referred for hysterectomy on a benign indication in Denmark from 2004 to 2009. Logistic regression was used to investigate associations of BMI with complications reported at surgery or during the first 30 days postoperative.

**Results** Of the 20,353 women with complete data, 6.0% had a BMI <20 kg/m², 51.9% with BMI between 25 and 30 kg/m², were classified as overweight and 17.5% as obese with a BMI≥30 kg/m². The rate of complications was 17.6% with bleeding being the most common specific complication (6.8%). After adjustment for age, ethnicity, education, smoking, indication for surgery, uterus weight, ASA-classification, co-morbidity status, and route of hysterectomy, obesity was associated with increased risk of bleeding (OR=1.27 (1.08–1.48) and infections (OR=1.47 (1.23–1.77). The risks of bleeding (OR=1.48 (1.28–1.72)) and re-operation (OR=1.67 (1.28–2.17)) were also increased among women with a BMI≥20. The U-shaped relation between BMI and bleeding, and between high BMI and infections were only seen for the abdominal route. The risk of infections was elevated among women with BMI <20 who underwent laparoscopic surgery.

**Conclusion** Obesity increases the risks of bleeding and infections after abdominal hysterectomy. A BMI below 20 seems to increase the risks of bleeding and infection after abdominal and laparoscopic hysterectomy, respectively.

**Combined Influence of Physical Activity and Hip Circumference on All-Cause Mortality**

**Introduction** Hip circumference has been shown to be inversely associated with mortality. Reduced femoral fat or muscle atrophy in the gluteofemoral region in those with narrow hips has been proposed as explanations and thus, physical activity is likely to play an important role. The aim was to estimate the combined effects of physical activity and hip circumference on mortality.
