lower BMI (difference between children of smoking vs non smoking fathers, 0.8 kg/m², 95% CI 0.1 to 1.4) and children of mothers reporting vigorous physical activity had lower BMI, cholesterol, ApoB/ApoA1 levels and decreased odds for overweight/obesity. Independent and consistently statistically significant associations were found between parents' and children's CVD risk-factors.

**Conclusion** Parental behaviours like smoking, alcohol consumption, and low physical activity were significantly associated with higher levels of certain CVD risk-factors in children. Strong correlations in CVD risk-factors between family members that are not related to SEP or parental lifestyle suggest a role of genetics in influencing children's CVD risk-factors. Public health policies should target families with unhealthy lifestyles.

**P2-139** PERIODONTAL INFLAMMATIONS ARE RELATED TO NITRIC OXIDE LEVELS IN SALIVA

doi:10.1136/jech.2011.142976i.74

**Introduction** Nitric oxide (NO) plays an important role in almost every biological system. The increase in NO in periodontal tissues has been reported in inflammatory periodontal disease, which suggests the production and participation of NO in the disease process. However, the association between salivary NO levels and periodontitis was rarely reported. The aim of this study was to assess the periodontal health according to the salivary NO levels in Korean elderly.

**Methods** 203 subjects aged 48–84 years old were cross-sectionally surveyed. All participants underwent oral examination. Age, gender, education level, regular exercise, smoking were evaluated through interview. Periodontal health status was evaluated by clinical attachment loss over 6 mm (CAL6 mm) for 6 points of 12 index teeth (total 72 sites). The number of CAL6 mm sites was counted. Unstimulated saliva was collected for 10 min. Salivary NO was determined by the Griess reagent. ANCOVA and Multiple linear regression analyses were applied.

**Results** After correcting for differences in for age, gender, education, regular exercise, smoking, salivary flow rate, and number of natural teeth, high NO level group showed the highest number of CAL6 mm sites (15.2 vs 7.0 and 10.8, p=0.031). Salivary NO levels had a dose-effect relationship with the number of CAL6 mm sites ($\beta$=0.026, p=0.011).

**Conclusion** NO levels are elevated in individuals with periodontitis. These results reveal that periodontal disease and its severity are related to salivary NO concentration, indicating that NO may serve as a potential biological marker for detection and monitoring of periodontitis.

An increasing number of studies in Western countries have examined the relationship between dietary pattern, namely the measurement of overall diet by considering the cumulative effects of nutrients, and the risk of metabolic syndrome (MetS). However, such information is absolutely lacking among Asian populations, including Korea, with different subject characteristics and culture-specific dietary habits. This cross-sectional study examined the association between dietary pattern identified by factor analysis and the risk of MetS among Korean population. We used data from the Korean National Health and Nutrition Examination Survey, 2007–2009. The analytical sample included men and women aged 30–80 years with 24 h recall, anthropometric and clinical measurements (n=5320). MetS was defined based on the Adult Treatment Panel III of the National Cholesterol Education Program criteria as having three or more risk factors using a modified obesity index. We identified three dietary patterns (“Meat & alcohol”, “Unbalanced Korean”, and “Diverse”) in both sexes. After adjustment for potential confounding factors, subjects in the highest quintile of the “Diverse” dietary pattern had significantly lower risk of MetS compared with those in the lowest in both sexes (multivariate OR: 0.50; 95% CI 0.27 to 0.90; p for trend =0.174 for men; multivariate OR: 0.58; 95% CI 0.38 to 0.87; p for trend =0.005 for women). Other dietary patterns were not associated with the risk of MetS. The result suggests that a diet high in vegetables, fruits, eggs, fish, and meat might reduce the risk of MetS among Korean population.
