had received therapy were interviewed face to face in Persian using a semi-structured interview guide. Interviews were audio taped, then transcribed in full, translated into English by the investigator, and analysed using MAXqda software.

**Results** The value men accorded to early detection of prostate cancer was found to be conditional upon their beliefs of prostate illness and their experiences about cure. There was a lack of information about the early detection process. The men felt that medical intervention was focused on the biological aspects, ignoring the needs of the psychosocial concerns. The men were not expecting to have symptoms because of prostate treatment; this influenced their subsequent decision-making.

**Conclusion** Given men’s perceptions and experiences of the illness, screening of prostate cancer seems to have wider implications. The findings suggest that early detection of the disease in Iran may need a screening model that incorporates both biomedical and psychosocial aspects.

### P2-301 HIGH PREVALENCE OF SEDENTARINESS AMONG BRAZILIAN ADOLESCENTS LIVING WITH HIV/AIDS

**Introduction** Several studies have shown high prevalences of sedentariness among adolescents, however, studies assessing sedentariness of adolescents with HIV are scarce. The aim of this study is to assess the prevalence of sedentariness in this population and its associated factors.

**Methods** 91 patients aged 10–19 years responded to the questionnaire on physical activity validated for Brazilian adolescents. The questionnaire is comprised of 17 questions (15 on sports and two on transportation physical activity). The cut-off point for sedentariness was 300 min/week.

**Results** Mean age at interview was 15.1 years (SD=2.6 years). A greater proportion of girls was sedentary (80%×61%, p<0.05). All other variables tested were not associated with sedentariness: ethnicity (white-65%, non-white-62%, p=0.236); living with family (yes-70%, no-59%, p=0.220); altered waist circumference (yes-70%, no-72%, p=0.881) and overweight (yes-0%, no-8%, p=0.081). No differences between means of biochemical parameters were found when comparing active and sedentary adolescents: viral load (15959×15922 copies, p=0.995); CD4 (485×441 cells, p=0.540); total cholesterol (156×162 mg/dl, p=0.523); HDL-cholesterol (59×57 mg/dl, p=0.375) and LDL-cholesterol (94×95 mg/dl, p=0.084). 1/3 of adolescents spent no time practicing physical activity. Among those who reported practicing it, the sports most cited were: football (44.4%), volleyball (14.4%) and cycling (7.8%). Mean time spent practicing sports was 198.9 min/week (SD=271.1 minutes) and mean time spent walking/cycling to school was 74.1 min/week (SD=104.2).

**Conclusion** A high prevalence of sedentariness was found in this population. Sedentary behavior may have a negative impact on adolescents’ health.

### P2-302 NOCTURNAL INTERMITTENT HYPOXIA AND CARDIOVASCULAR RISK FACTORS IN COMMUNITY-DWELLING JAPANESE: THE CIRCULATORY RISK IN COMMUNITIES STUDY (CIRCS)

**Introduction** To investigate whether nocturnal intermittent hypoxia (NIH), a surrogate marker for sleep apnoea, is associated with cardiovascular risk factors, we conducted epidemiological studies.

**Methods** The CIRCS is a prospective cohort study across Japan since 2003 to examine risk factors for cardiovascular disease. Subjects aged 40–69 years were recruited to the sleep study in three communities. NIH was estimated by hourly occurrences of oxygen desaturation of ≥3% (8% oxygen desaturation index [8% ODI]) by a pulse-oximeter during a night’s sleep in the participant’s own home. We defined no, mild and moderate-to-severe NIH by 3% ODI as <, 5 to <15 and ≥15 events/h, respectively. We conducted cross sectional studies on...
