**P2-389** USE OF HEALTHCARE IN A SOCIAL NETWORK OF MEN WHO HAVE SEX WITH MEN IN BRAZIL

doi:10.1136/jech.2011.142976.l.19

T.Dzebisashvili. *Moscow Regional Research Clinical Institute, Moscow, Russia

**Aims** To assess RR of type 2 diabetes (T2DM), overall and acute cardiovascular mortality and cardiovascular events in persons with impaired fasting glucose (IFG) and impaired glucose tolerance (IGT).

**Materials and Methods** According to population based study among 2508 adults, the 3-year risk of T2DM, overall and acute cardiovascular mortality and cardiovascular events (fatal and nonfatal) myocardial infarction and stroke, coronary heart disease was estimated in people with glucose metabolism abnormalities (GMA): IFG, IGT, IFG+IGT diagnosed in 2006 in comparison with normal glucose tolerance. RR and regression coefficient (B) was calculated using Cox-regression analysis. RR of T2DM, cardiovascular events was adjusted for age, sex, BMI, systolic blood pressure (SBP), smoking.

**Results** Highest adjusted RR of T2DM were in IFG+IGT (11.2 [9.95-13.6], p<0.01). Lowest RR of T2DM were in isolated IGT (3.92 [1.11-13.90], p=0.004). Adjusted RR of cardiovascular mortality was significantly 3.2-fold higher in IFG. IGT and newly diagnosed T2D had significantly 3.6-fold and 2.5-fold greater risk of overall mortality. RR of cardiovascular events was significantly increased 2.2-fold in IFG and 2.7-fold in T2D. There was not linear association between blood glucose levels and cardiovascular mortality risk (p=0.095) in contrast to the continuous linear relationship observed between blood glucose levels and coronary heart disease risk B=0.273 (p=0.001).

**Conclusion** 3 year risk of T2DM is not equal at different early GMA: highest one—in IFG+IGT, lowest—in isolated IGT. IFG increased 3-year risk of acute cardiovascular mortality. There was not linear association between blood glucose levels and cardiovascular mortality risk.

**P2-391** HBA1C FOR DIABETES MELLITUS DIAGNOSIS

doi:10.1136/jech.2011.142976.l.21

**Public Health Institute, Federal University of Bahia, Salvador, Bahia, Brazil; 2 Fiocruz Foundation, Ministry of Health, Rio de Janeiro, Rio de Janeiro, Brazil; 3 Medical School, Federal University of Ceara, Fortaleza, Ceara, Brazil

**Introduction** It is known that men access health services less frequently than women. According to WHO it is even less frequent among men who have sex with men (MSM) which increases the vulnerability of this group to HIV/AIDS and other STD.

**Methods** To describe the use of healthcare on HIV/STD among MSM, data were collected using respondent driven sampling as part of the baseline of the Brazilian behavioural and serologic surveillance survey of 3859 MSM in 10 cities in 2009. The analyses, conducted with 385 MSM from a major capital city—Salvador, Northeast Brazil, used a complex network theory, specifically two-mode networks with bipartite graph, classic statistics analysis of networks and projection.

**Results** Among the participants, 57% referred to have access to general health services, with 55% of them having had at least one medical appointment within the past 2 years. Over half (56%) did not know where to go for an HIV test; and 44% had an HIV test in the past year. Among those, 25% tested in a public health clinic, and 64% were given free condoms on the same facilities.

**Conclusion** To improve access to healthcare and to HIV testing among MSM is crucial to tackle the epidemic in Brazil, especially with the high HIV prevalence (12.6%) reported in the country among this population group.

**P2-392** RISK FACTORS FOR DIABETES AND PREDIABETES

doi:10.1136/jech.2011.142976.l.22

T Dzebisashvili. *Moscow Regional Research Clinical Institute, Moscow, Russia

**Aim** To estimate risk factors for developing type 2 diabetes (T2D), impaired glucose tolerance (IGT), impaired fasting glucose (IFG) and combination IGT+IFG.

**Material and Methods** A population-based screening for glucose metabolism impairments (GMI) among 661 adults in Moscow Country was conducted in 2009. HbA1c was determined in 39 subjects with GMI.

**Results** Based on OGTT and HbA1c, 6 and 11 people had T2DM; 33 and 23 people had prediabetes. Mean HbA1c (SD) was 7.9 (2.8) for T2DM, 6.0 (0.5) for IGT and 5.8 (0.7) for IFG and 6.5 (0.5) for IGT+IFG. The sensitivity/specificity (Sn/Sp) of HbA1c >6.5 for T2DM were 66%/78%, Sn/Sp of HbA1c >5.7-6.4% for IGT were 68%/64%, for IFG were 50%/42% and for IGT+IFG were 50%/42%.

**Conclusion** OGTT and HbA1c are both relevant diagnostic criteria for dysglycemia as they correlate with the risk for developing T2DM. Choosing the HbA1c strategy rather than the OGTT strategy leads to diagnose more diabetes, although the consistency of both diagnostic criteria is low. The optimal HbA1c cut-point to detect T2DM was lower than HbA1c of 6.5% in normal weight individuals.
