**Conclusion**
This study indicated that Ca level in breast milk might be associated with the underweight at 6 months old in rural Bangladesh.

**P2-389 USE OF HEALTHCARE IN A SOCIAL NETWORK OF MEN WHO HAVE SEX WITH MEN IN BRAZIL**

T Dzebisashvili.* †Moscow Regional Research Clinical Institute, Moscow, Russia

**Aims**
To evaluate diagnostic strategy with OGTT and/or HbA1c for detecting undiagnosed T2DM.

**Materials and Methods**

**Results**
Based on OGTT and HbA1c, 6 and 11 people had T2DM; 33 and 23 people had prediabetes. Mean HbA1c (SD) was 7.9 (2.8) for T2DM, 6.0 (0.5) for IGT and 5.8 (0.7) for IFG and 6.5 (0.5) for IGT + IFG. The sensitivity/specificity (Sn/Sp) of HbA1c >6.5 for T2DM were 66%/78%, Sn/Sp of HbA1c >5.0–6.4% for IGT were 68%/64%, for IFG were 50%/42% and for IGT + IFG were 50%/42%. Using ROC curve analysis, the optimal single HbA1c cut-point for detecting T2DM was >6.0%, (Sn/Sp: 50%/100%), for IFG was <5.5% (Sn/Sp: 50%/100%) in normal weight (BMI 18–25) individuals.

**Conclusion**
OGTT and HbA1c are both relevant diagnostic criteria for dysglycemia as they correlate with the risk for developing T2DM. Choosing the HbA1c strategy rather than the OGTT strategy leads to diagnose more diabetes, although the consistency of both diagnostic criteria is low. The optimal HbA1c cut-point to detect T2DM was lower than Hba1c of 6.5% in normal weight individuals.

**P2-390 CARDIOVASCULAR AND DIABETES RISK IN PERSONS WITH PREDIABETES**

T Dzebisashvili.* †Moscow Regional Research Clinical Institute, Moscow, Russia

**Aim**
To assess RR of type 2 diabetes (T2DM), overall and acute cardiovascular mortality and cardiovascular events in persons with impaired fasting glucose (IFG) and impaired glucose tolerance (IGT).

**Materials and Methods**
According to population based study among 2508 adults, the 3-year risk of T2DM, overall and acute cardiovascular mortality and cardiovascular events (fatal and nonfatal myocardial infarction and stroke, coronary heart disease) was estimated in people with glucose metabolism abnormalities (GMA): IFG, IGT, IFG+IGT diagnosed in 2006 in comparison with normal glucose tolerance. RR and regression coefficient (B) was calculated using Cox-regression analysis. RR of T2DM, cardiovascular events was adjusted for age, sex, BMI, systolic blood pressure (SBP), smoking.

**Results**
Highest adjusted RR of T2DM were in IFG+IGT (11.2 [3.9–31.65], p<0.01). Lowest RR of T2DM were in isolated IGT (3.92 [1.11–13.90], p=0.064). Adjusted RR of cardiovascular mortality was significantly 3.2-fold higher in IGT. IGT and newly diagnosed T2D had significantly 3.6-fold and 2.3-fold greater risk of overall mortality. RR of cardiovascular events was significantly increased 2.2-fold in IGT and 2.7-fold in T2D. There was not linear association between blood glucose levels and cardiovascular mortality risk (p=0.095) in contrast to the continuous linear relationship observed between blood glucose levels and coronary heart disease risk B=0.273 (p=0.001).

**Conclusion**
3 year risk of T2DM is not equal at different early GMA: highest one—in IFG+IGT, lowest—in isolated IGT. IFG increased 3-year risk of acute cardiovascular mortality. There was not linear association between blood glucose levels and cardiovascular mortality risk.

**P2-391 HBA1C FOR DIABETES MELLITUS DIAGNOSIS**

**Aim**
To estimate risk factors for developing type 2 diabetes (T2D), impaired glucose tolerance (IGT), impaired fasting glucose (IFG) and combination IGT+IFG.

**Materials and Methods**
A population-based screening for glucose metabolism impairments using standard 2-h OGTT among 2508 adults in Moscow County was conducted. BMI, waist circumference (WC), systolic and diastolic blood pressure were estimated. Lipids (total, LDL, fasting triglycerides (TG)) measurements were performed among 661 persons. Also participants fill forms about other risk factors. RR of T2D, IFG, IGT and unstandardised regression coefficient (B) was calculated using Cox-regression analysis. SPSS V13.0 (adjusted for BMI and age). RR was considered significant if confidential interval was not included 1 and p<0.05.

**Results**
Risk factors for T2DM and prediabetes was age, BMI, systolic blood pressure. Also risk factors for T2DM was ischaemic heart disease, family history of diabetes, alcohol consumption, diastolic blood pressure (DBP), waist circumference (WS), raised triglycerides, reduced smoking (B=−0.374, p=0.052). Risk factors for IGT was DBP, oral contraceptives. Risk factors only for IFG was physical inactivity, gender. Risk factors for IGT+IFG was budget, DBP, WS in men.

**P2-392 RISK FACTORS FOR DIABETES AND PREDIABETES**
