Background

Non-communicable diseases are increasingly recognised as the major health issue facing many governments. Brazil has observed a rapid change in the weight profiles of its population, with the prevalence of obesity and overweight increasing partly as a result of the well-documented effect of the nutrition transition. Obesity-related diseases are placing a substantial health and economic burden on the country. While the problem has been recognised, the implications of current trends on future overweight and obesity rates, BMI-related disease and costs associated with that disease burden have not been considered.

Methods

A previously developed micro-simulation model was used to project through the year 2050 the extent of obesity, BMI related diseases, and associated health care costs in Brazil. A Monte-Carlo simulation method has been utilized to simulate BMI related diseases. In total, thirteen conditions were modelled: coronary heart disease, stroke, hypertension, diabetes, knee osteoarthritis, and eight cancers (breast, kidney, colorectal, oesophageal, endometrial, gallbladder, liver and pancreas). The authors also projected a possible decrease in the BMI and its impact on health and health care costs.

Results

In 2010, nearly 45% of the Brazilian male population were overweight or obese (BMI ≥25 kg/m²), but by 2050 we project rates as high as 95%. A slightly less pessimistic picture is observed among females: 42% in 2010 increasing to 52% in 2050. The disease incidence figures increase considerably due to obesity patterns. However, BMI reduction across the population will alter these disease projections. Nearly three million diabetes cases and USD 388 million in health care expenditure can be avoided with a five percent reduction in BMI alone by 2050.

Conclusion

Obesity rates are rapidly increasing in Brazil creating a high burden of diseases and associated health care costs. However, even a one and percent reduction in prevalence rates will substantially reduce the disease and cost burden. Though some steps have been taken for tackling the obesity problem, Brazil still needs a strong, comprehensive policy involving multiple agencies and institutions with strong leadership.

OP22 PROJECTIONS OF HEALTHCARE COSTS IN THE LAST YEAR OF LIFE FOR OLDER CANCER PATIENTS IN EUROPEAN UNION MEMBER STATES (2008-2030)

H Petkova, D Dawoud, P McCrone, IJ Higginson. 1Department of Palliative Care, Policy and Rehabilitation, King’s College London, London, UK; 2Department of Palliative Care, Policy and Rehabilitation, King’s College London, London, UK; 3Health Service and Population Research Department, King’s College London, Institute of Psychiatry, London, UK; 4Department of Palliative Care, Policy and Rehabilitation, King’s College London, London, UK

Background

Despite advances, cancer remains a major cause of pain, suffering and death. The highest incidence and mortality occurs in older people (≥65), and given demographic change the numbers are expected to rise in the coming years. This has financial consequences and key implications for service planning. We estimated the current and future cost of providing care for older cancer patients in the last year of life (LYOL) in the 27 European Union (EU) member-states between 2008 and 2030.

Methods

Our cost projection models combined: a) WHO-GLOBOCAN mortality data; b) an average UK-based estimate of the cost of care per cancer patient in the LYOL; c) country-specific adjustment factor; d) annual cost inflation correction, range 5%–15%; 5% (conservative scenario), 10% (realistic scenario), 15% (highest expected increase scenario); and e) an adjustment for age to reflect the increasing life expectancy (LE) and the related morbidity expansion.

Results

The total EU cost of care for older cancer patients in the LYOL is expected to increase by 48% (2008–2030) reflecting mortality rates only (baseline model). Assuming 5% cost rise per year (model 1), we projected more than a two-fold increase in the total EU cost by 2030 at an average annual rate of 9.6%. Model 2 involved 10% inflation and no ageing-adjustment, predicting a 3.7 times cost rise during the next two decades. This equated an annual average increase at 16.9%. We predicted a slightly higher cost rise when we allowed for ageing in addition to the 10% annual inflation (model 3) at approximately 17% increase year on year. This represents $81 billion absolute increase during the projected period or $3.6 average annual increase for Europe as a whole. The highest cost increase is expected in model 4 (15% inflation with ageing-adjustment). Costs are predicted to rise more than five times between 2008 and 2030, marking a 24.3% average annual increase. There is a marked cost variation across Europe.

Conclusion

Costs of care for older cancer patients in the LYOL are projected to rise substantially in the foreseeable future. Our models outline cost variation between 2.2% and 24.3%, with the most realistic increase expected at 17% annually. This has key implications for short and medium-term service planning of how to provide care in the LYOL for the rising number of older citizens dying from cancer, taking into account the current economic climate in Europe.
