explain differences in all ages and premature CVD mortality between LAs in England.

**Methods**

All data were sourced for each LA in England. Outcome variables were age-standardised 2012 to 2014 CVD mortality for all ages and those under 75 (premature mortality). Prevalence of ethnic and socioeconomic groups from the UK 2011 census, Public Health England data on index of multiple deprivation (IMD) score, prevalence of smoking, physical activity and obesity/overweight and Ordnance Survey environmental data on percentage of food shops, eating out shops, green/blue space, sporting facilities and health facilities were sourced. We used the Akaike Information Criterion (AIC) to assess which types of variables provided the best statistical model to explain variation in CVD mortality between LAs then used multiple linear regression to assess which variables remained associated with the outcome.

**Results**

Including health, demographic, environment and IMD variables provided the best fit for explaining variation in CVD mortality at all ages, with an adjusted R^2^ of 0.63. For premature CVD mortality, excluding environmental data improved the fit of the model and gave an adjusted R^2^ of 0.82.

The percentage of Indian and Pakistani ethnic groups in LAs remained associated with all ages CVD mortality, along with higher scores for the employment domain and living environment domain of the IMD. For premature mortality, the percentage of Pakistani and Bangladeshi ethnic groups, excess weight prevalence and higher income and crime IMD scores remained associated.

**Conclusion**

Certain IMD domains and prevalence of some South Asian ethnic groups are important for explaining variation in age-standardised cardiovascular disease mortality at the LA level in England. These findings are valuable for understanding which factors to target to reduce inequalities in CVD mortality between LAs in England.

**IS IT FEASIBLE TO EVALUATE CARDIAC MRI IN PATIENTS WHO ACTIVATE THE PRIMARY PERCUTANEOUS CORONARY INTERVENTION PATHWAY USING HOSPITAL EPISODE STATISTICS DATA?**

1M Pufulete, 1J Harris, 2S Dorman, 3R Brierley*, 4B Reesews. 1Clinical Trials and Evaluation Unit, University of Bristol, Bristol, UK; 2Bristol Heart Institute, University Hospitals Bristol NHS Foundation Trust, Bristol, UK; 3Southmead Hospital, North Bristol NHS Trust, Bristol, UK; 4St. George’s Vascular Institute, St. George’s Vascular Institute, St. George’s Healthcare NHS Trust, London, UK

10.1136/jech-2017-SSMAbstracts.138

**Background**

Cardiac magnetic resonance (CMR) imaging is a non-invasive test used to assess the structure and function of the heart. We tested the feasibility of assembling a retrospective cohort study of patients who activate the primary percutaneous coronary intervention (PPCI) pathway using data from Hospital Episode Statistics (HES) and Patient Episode Database Wales (PEDW) to: i) document the use of cardiac magnetic resonance (CMR) imaging in this population; and ii) determine whether CMR is associated with improved clinical outcomes.

**Methods**

Patients from four UK sites were recruited into the prospective cohort study. We assembled a database by linking routinely collected hospital data for the index PPCI admission (demography, clinical, biochemistry and imaging) with HES and PEDW describing inpatient and outpatient NHS episodes in the 12 months following the index PPCI admission. We determined whether we could identify the following from HES/PEDW data: i) the index event (cohort entry); ii) CMR within 10 weeks of the index event (exposure); iii) relevant subgroups of the population (e.g. PPCI, unobstructed coronary arteries, multivessel disease, cardiac arrest, etc.); and iv) clinical outcomes.

**Results**

A total of 1670 patients were recruited prospectively into the cohort study; of these 1612 (97%) had admission data in HES/PEDW that coincided with the index event (±1 day). Only 1227/1612 (76%) had HES/PEDW data that met the criteria for cohort entry; 1110 (91%) were identified as PPCI and 117 (9%) were identified as emergency angiography only. The remainder (385/1612, 24%) did not meet inclusion criteria (PCI procedure code and ST-elevation myocardial infarction subgroup).
infarction, STEMI, diagnostic code) or their angiography was not identified as an emergency. Hospital data documented that 187 patients had CMR but, in the HES/PEDW data (inpatient and outpatient), CMR was recorded for only 53 of these (28%). We are currently exploring algorithms to identify specific subgroups of particular interest with respect to CMR; early results suggest that we can identify patients who have had cardiac arrest or who have unobstructed arteries but not those with multivessel disease.

Conclusion It is possible to identify patients who activate the PPCI pathway from routinely collected HES/PEDW data. We conclude that it is not currently feasible to document the use of CMR in patients who activate the PPCI pathway from HES/PEDW data although the integration of the Diagnostic Imaging Dataset with inpatient and outpatient HES datasets may make it feasible soon. We are exploring the reasons for the discordance between CMR scans reported in the prospective cohort study and those identified in HES.

P37  BARRIERS TO AND FACILITATORS OF EFFECTIVE DIABETES SELF-MANAGEMENT AMONG PEOPLE NEWLY DIAGNOSED WITH TYPE 2 DIABETES MELLITUS (T2DM): A QUALITATIVE STUDY FROM MALAYSIA

1 AM Mohamed*, 2 J Roopi, 3 X Ismail, 4 K Winkel. 1 Department of Psychological Medicine, Institute of Psychiatry, Psychology and Neuroscience, King’s College London, London, UK; 2 Non-Communicable Disease Unit, Primary Care Clinic (Tampol), Johor Bahru, Malaysia

Background To determine the views and experiences of people with Type 2 diabetes (T2DM) in relation to their diabetes self-management and to understand what additional support is required to support lifestyle changes.

Methods A qualitative study using semi-structured face-to-face and audio/telephone interviews. All interviews were audio-recorded, transcribed verbatim and analysed using a thematic approach. Seventeen people with newly diagnosed T2DM (less than 3 years of diagnosis) were recruited from a primary care clinic in the southern region of Malaysia (Johor Bahru).

Results Qualitative analysis revealed three major barriers to diabetes self-management: (i) psychological issues, e.g. depression and anxiety, such as feeling sad about the diagnosis and worried about the future; (ii) social factors e.g. shame and stigma of T2DM, feeling ashamed have diabetes at a young age and being different from peers; (iii) perceived barriers e.g. environment and culture, such as ineffective support from healthcare providers, beliefs and use of herbal medicine, and the importance of eating rice and feast culture. Facilitators of diabetes self-management included greater perceived self-efficacy such as being disciplined about eating well, good support from immediate family members and religiosity.

Conclusion This study represents novel findings describing barriers and facilitators of effective T2DM self-management in Malaysia. It identifies specific cultural factors that are unique to the Malaysian population that have not been reported in western studies. If diabetes self-management education is to meet people’s needs within this region factors such as these need to be considered when developing new T2DM education programmes.

P38  DECISION REGRET IN MEN TREATED FOR LOCALISED PROSTATE CANCER: RESULTS FROM THE LIFE AFTER PROSTATE CANCER DIAGNOSIS STUDY

A Downing*, 1 P Wright, 2 E Watson, 3 R Wagland, 4 L Hounsome, 5 H Butcher, 6 A Gavin, 1 NW Glaser. 1 Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, UK; 2 Department of Applied Health and Professional Development, Oxford Brookes University, Oxford, UK; 3 Faculty of Health Sciences, University of Southampton, Southampton, UK; 4 National Cancer Registration and Analysis Service, Public Health England, London, UK; 5 Northern Ireland Cancer Registry, Queens University Belfast, Belfast, UK

Background Men with localised prostate cancer have a number of treatment options. Treatments carry associated benefits and side- and late-effects. The Life After Prostate Cancer Diagnosis study is a UK-wide survey of men 18–42 months post-diagnosis of prostate cancer. The survey included treatment questions, the Decision Regret Scale (DRS) and a single item on decision-making participation. The aim of this sub-study is to explore the association of decision regret with prostate cancer treatment and patient perception of participation in decision making.

Methods The English arm of the survey achieved a 60.3% response rate (30 463 respondents). Men diagnosed with stage 1–3 disease were included in this sub-study (n=16,808). Descriptive statistics were used to explore associations between DRS scores (0–100), self-reported treatments and perceived participation in decision-making.

Results 12 600 (75.0%) men completed the DRS. Due to the skewed nature of the data, decision regret was categorised as ‘None’ (score=0; 36.5%), ‘Low’ (score=5–20; 31.6%) and ‘High’ (score=≥25; 31.8%). Levels of regret were lowest in men who underwent brachytherapy alone and surgery alone (25.8% and 27.5% respectively reporting ‘High’ regret). Men who received combination therapy (e.g. radiotherapy and hormones) reported higher levels of regret compared to men having a single therapy (34.8% vs. 28.3% reporting ‘High’ regret). 28.6% of men on active surveillance reported a high level of regret. 74.2% of men said their views were definitely taken into account in treatment decisions: 22.6% of these reported high regret. 2.8% of men said their views were not taken into account; 62.8% reported high regret. 74.2% of men said their views were definitely taken into account in treatment decisions: 22.6% of these reported high regret. 2.8% of men said their views were not taken into account; 62.8% reported high regret.

Conclusion These preliminary analyses show a strong association between perceived involvement in treatment decision making and subsequent decision regret in men with prostate cancer. Levels of regret also vary according to the type of treatment received. Interestingly, men on active surveillance who receive no treatment report similar levels of regret to those who undergo surgery. Further analysis will investigate the impact of patient characteristics and functional outcomes (urinary, bowel and sexual) on levels of regret.

P39  EMERGENCY ADMISSIONS TO HOSPITAL FOR OLDER PEOPLE WITH COPD DURING THE RESHAPING CARE FOR OLDER PEOPLE PROGRAMME (RCOPP): AN ECOLOGICAL STUDY

KA Levin*, EM Crichton. Public Health Directorate, NHS GGC, Glasgow, UK

Background Patients with acute exacerbations of COPD are a common cause of emergency admissions to hospital. The RCOPP Programme was implemented in the UK in 2015 to reduce hospital admissions by encouraging primary care providers to develop multi-disciplinary care plans and to implement strategies to improve the management of patients with COPD. This study aims to evaluate the impact of RCOPP on hospital admissions for COPD episodes in England.

Methods This is a retrospective analysis of routinely collected data from the Hospital Episode Statistics (HES) for England, covering hospital admissions from 2010/11 to 2015/16. Data were stratified by age and COPD diagnosis.

Results The analysis showed a significant decrease in hospital admissions for COPD episodes in England during the RCOPP implementation period. The reduction was greatest in older people (≥65 years).

Conclusion The results of this study suggest that the RCOPP Programme has had a positive impact on reducing hospital admissions for COPD episodes in England.
