ALCOHOL CONSUMPTION AND RISK OF INCIDENT VITAMIN D DEFICIENCY, IMPAIRED LUNG FUNCTION

A total of 2544 community-dwelling older people aged 60 years and over. However, one potential weakness is that there was no definition in the questionnaire of what constituted a fall. This research will inform the development of interventions to reduce the risk of falls among older people.

Frailty was defined using Fried criteria on association between alcohol and frailty, which is still controversial. Therefore we investigated the relationship between alcohol consumption and the risk of incident frailty.

Methods A total of 2544 community-dwelling older people aged ≥60 years from the English Longitudinal Study of Ageing were followed for incident frailty over four years according to alcohol consumption. Frailty was defined using Fried frailty phenotype criteria with slight modification according to data availability. Questionnaire data on alcohol consumption was grouped into non-drinkers, >0–7 units/week, >7–14 units/week, >14–21 units/week, >21 units/week. Multivariable logistic regression models were used to examine incident frailty risk.

Results Compared with those drinking >0–7 units per week (reference), those drinking >21 units per week were less likely to develop frailty (Odds ratio (OR)=0.45, 95% confidence interval (CI)=0.27–0.73, p<0.001) in the unadjusted model, however the association became non-significant in the fully adjusted model controlling for age, gender, smoking, education and wealth (OR=0.65, 95% CI 0.38 to 1.11, p=0.12). There was no significant difference in incident frailty risk in those drinking >7–14 and >14–21 units per week compared to >0–7 units per week in any models. Non-drinkers had worse health profile and higher incident frailty risk than drinkers (fully adjusted OR=1.63, 95% CI 1.07 to 2.48, p=0.02).

Conclusion In this cohort non-drinkers had a significantly higher risk of developing frailty compared to light drinkers (>0–7 units per week). No significant associations were observed among drinkers. The true association between alcohol and frailty may have been affected by a ‘sick-quitter’ effect (i.e. drinkers who are ill health tend to reduce or cease alcohol use), which should be addressed in future research.

Background Chronic obstructive lung disease (COPD) is a common chronic inflammatory disease in the elderly and is a major cause of morbidity and mortality. Much attention has focussed on identifying factors which may influence prognosis and mortality in these patients. Although vitamin D deficiency (ascertained from measuring the circulating 25-dehydroxyvitamin D (25OHD) metabolite) and lung function impairment and assessed whether vitamin D deficiency is related to long term mortality in those with impaired lung function.

Methods Prospective study of 3575 men aged 60–79 years with no prevalent HF followed up for 15 years, in whom there were 1937 deaths (80 COPD deaths). The Global Initiative on Obstructive Lung Diseases (GOLD) spirometry criteria was used to define airway obstruction. Vitamin D deficiency was defined as serum 25OHD levels <10 ng/ml; insufficiency as 25OHD 10–19 ng/ml; normal as 25OHD ≥20 ng/ml.

Results Vitamin D deficiency was associated with moderate COPD (FEV1/FVC <70% and FEV1 50–80%) and severe COPD (FEV1/FVC <70% and FEV1 <50%) but not with mild COPD (FEV1/FVC <70% and FEV1 >80%) or restrictive lung disease (FEV1/FVC >70% and FVC <80%). Vitamin D deficiency was associated with significantly increased risk of total and COPD mortality in all men except those with severe COPD after adjustment for confounders. The adjusted HRs (95% CI) for total mortality comparing levels of 25OHD <10 ng/mL to 25OHD ≥20 ng/ml were 1.38 (1.10, 1.75), 1.62 (1.22, 2.15), 1.93 (1.32, 2.80) and 1.34 (0.78, 2.31) for those with none/mild COPD, restrictive lung function, moderate COPD and severe COPD respectively. The corresponding HRs (95% CI) for COPD deaths were 14.3 (2.43, 83.23), 5.10 (0.96, 27.06), 3.55 (1.12, 11.22) and 0.81 (0.25, 2.57) for the 4 groups respectively.

Conclusion Our findings suggest that older adults with vitamin D deficiency (<10 ng/ml) and earlier stages of lung impairment may potentially benefit from vitamin D supplementation. Intervention trials in older people with mild or moderate impaired lung function are needed to confirm whether increasing vitamin D levels through supplements in those with vitamin D deficiency will reduce both risk of COPD deaths and overall mortality.
