Results Social and cultural engagement were both independently associated with a lower risk of developing dementia in older age in fully-adjusted models. Using time-to-event analyses, socialising once a week was associated with a 29% lower risk OR=0.71 95%CI 0.52–0.97 and cultural engagement every few months or more was associated with a 42% lower risk OR=0.58 95%CI 0.41–0.80. Using competing risk models, socialising OR=0.80 95%CI 0.59–1.08 and cultural engagement OR=0.65 95%CI 0.47–0.90. Using modified Fine and Gray Subdistribution hazards models, socialising OR=0.66 95%CI 0.53–0.82 and cultural engagement OR=0.42 95%CI 0.32–0.56. Community group activities were only associated with dementia in minimally-adjusted models. Results were robust to sensitivity analyses considering moderators, reverse causality, over-adjustment, and baseline cognitive function.

Conclusion The results presented here suggest that social and cultural engagement are independent risk-reducing factor for the development of dementia in older age. Even for those who lack contact with friends and family or who socialise infrequently, engagement with cultural venues, even on a less frequent basis, could be protective against the incidence of dementia. These findings align with broader findings relating to cognitive reserve and support the development of multimodal community-based interventions to promote healthy cognitive ageing amongst older adults.

Results In the BRHS, having no natural teeth was associated with being in the top tertiles of CRP, and fibrin D-dimer (odds ratio (OR)=1.35, 95%CI: 1.01–1.80; OR=1.38, 95%CI: 1.03–1.85, respectively) after adjustment for age, social class, smoking, history of cardiovascular disease and diabetes, and BMI. Tooth loss (<21 teeth) was associated with being in the top tertiles of CRP, hsTnT, fibrin D-dimer, and NTproBNP (fully adjusted OR=1.31, 95%CI: 1.02–1.68; OR=1.32, 95%CI: 1.01–1.74; OR=1.37, 95%CI: 1.05–1.77, OR=1.40, 95%CI 1.01–1.94, respectively). Periodontal disease was associated with being in the top tertile of hsTnT. In the HABC Study, having no teeth and partial tooth loss were associated with being in the top tertile of CRP (OR=1.57, 95%CI: 1.10–2.25; OR=1.40, 95%CI: 1.13–1.75, respectively) after adjustment for age, gender, race, education, smoking, history of cardiovascular disease and diabetes, and BMI. Moreover, having ≥3 oral health problems was associated with being in the top tertiles of CRP and IL-6 after full adjustment.

Conclusion Poor oral health in older people was associated with increased levels of various inflammatory markers including CRP, fibrin D-dimer, hsTnT and NTproBNP. These findings suggest that poor oral health in older age is linked not only to general systemic inflammation but also inflammation associated with metabolic disturbances. These associations could offer insights into mechanistic pathways by which poor oral health could influence age-related conditions.

Mental Health 1

Background Hospital management of self-harm is an essential component of suicide prevention. Patients presenting to hospital for self-harm involving highly lethal methods or with high suicidal intent are a subgroup of self-harm patients at high risk of suicide. Investigating healthcare service provision from the patients’ perspective is integral to the design and implementation of better quality care. The current study explored patients’ experiences of engaging with healthcare services after a high risk self-harm presentation to hospital.

Methods A sequential transformative mixed-methods design was used. Quantitative information was obtained by interview administered questionnaires (including internationally validated scales, closed and open-ended questions) 0–3 months following a high risk self-harm presentation to a hospital emergency department (n=67). Semi-structured follow-up interviews were conducted 6–9 months later providing qualitative data (n=31). Follow-up interviews were recorded, transcribed and thematically analysed using NVivo software. Quantitative information was analysed in SPSS Version 25. Both methodologies were integrated during the interpretation of the results.

Results After the self-harm presentation, 85.7% of patients reported receiving follow-up care with public outpatient mental health services and 61.8% attended their general
