in particular in relation to people with more than two of these experiences and for health outcomes other than infections. This situation is exacerbated by the under-ascertainment of these populations in routine information sources on population health needs, such as surveys and censuses. In many countries, administrative data are available which could help address these knowledge gaps. We describe the creation and characteristics of a novel virtual cohort using cross-sectoral linkage of administrative datasets, in order to inform policy and practice responses to these co-occurring issues.

**Methods** Individual-level data from local authority homelessness services (HL), opioid substitution therapy dispensing (OST), and a psychosis case register (PSY) in Glasgow, Scotland between 2011–15 were confidentially linked to National Health Service records, using a mix of probabilistic and deterministic linkage. A de-identified dataset was made available to researchers through a secure analysis platform. Demographic characteristics associated with different exposure combinations were analysed using descriptive statistics.

**Results** Linkage created a cohort of 24,767 unique individuals with any one of the experiences of interest between 2011–15. Preliminary results suggest that 89.2% of the cohort had one experience; 10.6% two; and 0.2% all three. The most common combination was HL & OST (n=2,150; 8.7%), with other combinations much less frequent (HL & PSY, n=279, 1.1%; OST & PSY, n=188, 0.8%; HL & OST & PSY, n=51, 0.2%). The odds of male gender increased with number of exposures (2 exposures, OR 2.1, 95% CI 1.9–2.2; 3 exposures, OR 4.1, 95% CI 2.3–7.2), but there was little difference in age. Work is ongoing to incorporate into the cohort additional datasets on criminal justice involvement.

**Discussion** Administrative data linkage is a feasible approach to understanding the health of people affected by multiple exclusionary processes, addressing problems of recruitment and retention affecting traditional cohort studies in this field. As well as improving the validity of descriptive epidemiology for these populations, this study offers a foundation for evaluating welfare and policy implications.
**Methods** We did a causal mediation analysis using data from the UK CF registry, which captures 99% of all people with CF in the UK and records clinical information including weight and infection status at annual review visits. The exposure of interest was SEC in the first year of life measured by the index of multiple deprivation; the outcome was first lung function measure between ages 6 and 9. We were interested in mediation by weight trajectory during the first six years of life. Potential confounders were sex, year of birth, genotype and infection.

All children born between 2000 and 2010 and diagnosed by newborn screening were included in the analysis if they had at least one lung function measure between ages 6 and 9, at least one weight and infection measure between birth and age 6, and complete data on SECs and baseline confounders. We imputed missing data using multiple imputation by chained equations.

We used the parametric mediational g-formula to estimate the total effect of SECs on lung function, and the indirect effect mediated by weight trajectories in the first six years of life, accounting for potential time-varying confounding by infection. Confidence intervals were estimated using non-parametric bootstrap.

**Results** Using data from 853 children, we found a total effect of deprivation on lung function, measured by percent of predicted FEV1, of 4.53 percentage points (95% CI 3.44 to 5.77). Our results showed that if we could improve the weight of the most disadvantaged children to have the same distribution as that of the least disadvantaged children, their lung function would improve on average by 0.74 percentage points (95% CI 0.36 – 1.1).

**Conclusion** Only 16% (95% CI 8%-25%) of the inequalities in early lung function for people with CF were explained by weight trajectories in the first 6 years of life, suggesting that other important pathways to inequalities need exploration.

#### OP23 THE LESSER-KNOWN BREASTFEEDING PROBLEM: PREVALENCE AND DETERMINANTS OF PRELACTEAL FEEDING PRACTICE IN INDONESIA

10.1136/jech-2020-SSMabstracts.23

**Background** Prelacteal feeding (PLF) is anything other than breastmilk given to neonates before breastfeeding is established. There are numerous types of PLF and they are given for various reasons. Except when medically indicated, PLF is considered as one of the many potential barriers to optimal breastfeeding. However, PLF is practiced widely across the world. Meanwhile, it is still understudied and epidemiological research on the different types of PLF is limited in many settings, including in Indonesia. This study looks at the prevalence and determinants PLF in Indonesia, focusing on overall PLF and three common types (formula, other milk, and honey).

**Methods** A cross-sectional, secondary data analysis of the 2017 Indonesia Demographic and Health Survey was undertaken. The study population was 6168 ever-breastfeeding mothers whose last child was ≤23 month-old. Because PLF was a common outcome, modified Poisson regression was used to estimate the adjusted prevalence ratio (PR) for potential determinants and PLF.

**Results** By 2017, nearly half (45%) of mothers in Indonesia gave PLF. The most common feeds were infant formula (25%), any other milk (14%), plain water (5%), and honey (3%). Factors associated with higher prevalence of overall PLF were upper-middle (Q3-Q4) wealth quintiles (PR 1.17, 95% Confidence Interval (CI) 1.03–1.32 for Q3 and PR 1.18, 95% CI 1.04–1.33 for Q4), rural residence (PR 1.17, 95%CI 1.07–1.27), baby perceived to be small at birth (PR 1.26, 95%CI 1.14–1.38), and caesarean deliveries at either public (PR 1.34, 95%CI 1.19–1.51) or private facilities (PR 1.17, 95%CI 1.03–1.33). Conversely, mothers who gave birth to the second/subsequent child (PR 0.81, 95%CI 0.75–0.87) and mothers who had at least one weight and infection measure between birth and age 6, and complete data on SECs and baseline confounders.

We imputed missing data using multiple imputation by chained equations.

We used the parametric mediational g-formula to estimate the total effect of SECs on lung function, and the indirect effect mediated by weight trajectories in the first six years of life, accounting for potential time-varying confounding by infection. Confidence intervals were estimated using non-parametric bootstrap.

**Results** Using data from 853 children, we found a total effect of deprivation on lung function, measured by percent of predicted FEV1, of 4.53 percentage points (95% CI 3.44 to 5.77). Our results showed that if we could improve the weight of the most disadvantaged children to have the same distribution as that of the least disadvantaged children, their lung function would improve on average by 0.74 percentage points (95% CI 0.36 – 1.1).

**Conclusion** Only 16% (95% CI 8%-25%) of the inequalities in early lung function for people with CF were explained by weight trajectories in the first 6 years of life, suggesting that other important pathways to inequalities need exploration.

#### OP24 THE MEDIATING PATHWAYS OF THE ASSOCIATION BETWEEN ADVERSE CHILDHOOD EXPERIENCES AND COGNITIVE HEALTH IN LATER LIFE

D Cadar, U Kobayashi, AP Steptoe, PD Demakakos*. 1Department of Behavioural Science and Health, University College London, London, UK; 2Department of Epidemiology, University of Michigan School of Public Health, Ann Arbor, Michigan, USA; 3Department of Epidemiology and Public Health, University College London, London, UK

10.1136/jech-2020-SSMabstracts.24

**Background** Previous research has often shown that morbidity and disability are hinged to negative events and exposures that can accumulate over the life course, but less clear is their impact on late-life cognitive health. We assessed the biopsychosocial mechanisms influencing the associations between adverse childhood experiences and cognitive impairment at advanced ages.

**Methods** Data were from 3,130 dementia-free adults aged 50+ from the English Longitudinal Study of Ageing (ELSA) with data available from wave 3 (2006/07) to wave 8 (2016/17). ELSA provides a wide variety of psychosocial data collected via face-to-face computer-assisted personal interviews (CAPI) and self-completion questionnaires. All participants provided informed consent prior to their participation in the study. We used structural equation modelling to estimate direct and indirect associations between adverse childhood experiences (ACEs) and cognitive impairment (measured with 1.5 SD below the mean on the modified Telephone Cognitive Screening Interview scale range 0 to 35) via markers of SES (education and wealth), inflammation (serum fibrinogen and C-
